> " If my husband were only different The night our Ken was killed, he went out and got drunk The police brought him home, and all the neighbours watching Next day he shut me up when I started to speak Then he's a good bit older than me too It's queer to explain, he was never much for married life even before, but after that, well, there hasn't been anything "

Do not break new ground by altering the treatment The usual bottle is best Separate symptoms cannot be obliterated by recent drugs Such methods may have a rapid rebound

> " I'm sorry to get you out so late, doctor, but I've felt that funny all evening If I shut my eyes, I can feel my head floating away I just took the first of those new shiny tablets when I got back from the surgery I couldn't have got up to the surgery, doctor, I wouldn't have dared Been on the go all night My husband said could it be those torpedo things you gave me?"

Referring them to hospital is seldom helpful

> " Oh, they were certainly very thorough down at the hospital, doctor First a young chap comes along and asks me about all the illnesses I have had, right back from my being little He was writing away for ages Then there was a bit where we was at cross-purposes, as it were, me telling him about that trouble Dad had down below, and him thinking it was me Then he had me in a little room stripped off, and he went over me from top to bottom, as you might say He left me standing there just as I was for quite a bit, while he went away Then back he came with a big dark fellow with a beard Gave me a nasty turn He feels my head all over, gentle like, then he taps it round a bit, then he listens in with those tube things They stood arguing it out after that, and in the end, they sent me for an X-ray photo of my head, but they couldn't see anything there "

* * *

Secure packaging of drugs is desirable, and for drugs for injection essential But must they be secured even from access by the doctor? The opening of glass ampoules is achieved at peril of lacerated fingers, but pride of place goes to the assortment of opaque media used by radiologists for injection into the various natural—and unnatural—orifices of the body

When another bottle is needed, the whole procedure, and the attendant team, has to wait while some trembling minion applies in turn Spencer Wells, pointed and blunt scissors, screwdriver, and marlinspike in an attempt to remove the metal ring from around the rubber cap Many opaque media are now available Not the least important consideration in making my choice is the ease with which I can get at the contents of the bottles

* * *

Once a year our local ferryboat has to be overhauled. Fifty weeks of shuttling back and forth across the lake seem to do something to its innards that merits an extensive laparotomy. I think perhaps frustration plays some part in its need for periodical therapy. You see it winds itself backwards and forwards across the lake on two stout cables anchored to either shore. On the east is where it was given birth with the labour pangs of its first shovelful of coal raising the puff of steam to breathe life into a hulk of embryonic steel. On the west is where its predecessor lies broken and rotting—where our own boat will be towed some day. But it is no use brooding on birth and death, life must be lived in between. So our little ferryboat chugs out all its energies on a fixed time-table, on a fixed route, day after day after day, a chain on either side. Can you wonder that it develops behaviour problems?

Anyway, when overhaul time comes round we have to leave the car on the shore and take the little carefree motor launch that the ferry-owners provide instead. Charon still collects an obolus with one hand and steers with the other, but crossing our lake in the dark is worse than any nine rivers in the underworld. It was foggy last Monday night when we set out from the eastern shore for the five-minute passage. After seven and a half minutes we were straining our eyes for the shore, after ten we were getting the wind up. Charon looked distinctly worried himself. He cupped his hands and shouted ahoy there in the best nautical tradition. Echoes from the hillside mingled with a plaintive inquiry as to what in hell Charlie thought he was doing out there, but the earthbound voice could not be further persuaded to define his location beyond the fact that he was *here*, and wherever that may have been was lost again in the swirling fog. At last we ran aground on an island Charlie knew, so we backed off and guessed our way a quarter of a mile south to the ferry's normal route. As we loomed up alongside the regular ferryboat, still in its chains, on the side of the lake where we had embarked, I thought I heard a scornful remark that some people do not know what to do with their freedom when they have got it.

* * *

Having been "kissed better" by Mummy on many occasions, my two-year-old, Elizabeth, assumes that modern medicine as practised by Daddy uses a similar technique. Our friends and neighbours are often reminded that "Daddy kisses his patients better". I hope none complain to the G.M.C.

* * *

The really annoying thing about those flimsy blue airmail letters is that they never can be made to fold properly. When I have carefully filled every square inch of the precious paper, and obediently written my name and address on the back, my troubles are only just beginning.

I flatten it out on the table and read the instructions carefully. "First fold here." I fold, taking care to fit the fold precisely to the line. Then, to my annoyance, the opposite edges do not go exactly into the corners of the gummed bit. I have to admit defeat over this, and proceed to "Second fold here". The same thing happens. When I lick the flaps and fold them, the folds never coincide with the dotted line, and it is always with a feeling of despair that I post the finished article.

The problem doesn't seem to bother my correspondents. They gaily slap their letters together, fail to put their addresses on the back, and even write in pencil; the letters arrive just the same. I sometimes wonder if it's worth it.

* * *

Life's not all jam being an identical twin. When last week my other half had a hæmorrhoidectomy it wasn't only the measles epidemic which kept me on my toes. However, two tags came off last night, and with luck any day now my vicarious suffering will be over, the air-ring discarded, and I'll be able to sit and drive again in comfort.

How green the field at Richmond on that day
When Thomas's did break The London's heart,
How green that Tommy's misbegotten fan
Who called the brewer's dray a grocer's cart.

Letters to the Editor

FLUORIDATION

SIR,—In the article in your issue of March 12 (p. 590) the difficulty experienced in finding suitable control communities is put forward as one of the reasons why satisfactory statistical experiments have not been carried out. There are, however, in the South Lincolnshire area, which is referred to in the article, communities very close to one another which would be most suitable for control and experimental studies because they receive water with a fluorine concentration varying from 0·5 p.p.m. to 3·5 p.p.m.

This is due to the fact that the bores that supply that area yield water of an increasingly high fluorine content as one passes from Bourne to Spalding. As a result, some towns such as Donnington and Spalding receive water with a fluorine content of about 0·5 p.p.m. whereas Crowland and the Deepings receive water with a fluorine content of 3·5 p.p.m.

While working in this area, the school dental officer and I undertook a few simple comparative studies in Crowland and Donnington, which have populations of about 3000 each and are only 15 miles apart as the crow flies. We found that the incidence of dental caries per child was much higher in Donnington than in Crowland, and that in Crowland mottling was generally mild among children whose main drink was milk, but severe among those whose main drink was tea or "fruit squash". We also found that the number of deaths from carcinoma of the stomach in Crowland over a 10-year period was more than twice as high as in Donnington over the same period. Deaths from all other causes occurred equally in the two towns.

I should like to stress that these are merely the observations of a rural epidemiologist, and would probably be disproved by careful statistical studies. There is undoubtedly a considerable amount of material to be studied in the South Lincolnshire area, and I feel that a long-term investigation of the dental health of the people in that area would provide some useful information on the effects of fluoridation.

RAISED INTRACRANIAL PRESSURE ASSOCIATED WITH TRIAMCINOLONE

SIR,—The undoubted value of prolonged steroid therapy must always be weighed against its known hazards, particularly in the growing child. The recognised effects include retardation of bone growth and osteoporosis; the newer compounds may produce quite unexpected complications. Valentine[1] suggested that triamcinolone had produced intracranial hypertension in a child with nephrosis. We believe that we have encountered this effect in two children, and we know that it has been recognised at Dr Lawson Wilkins' clinic in Baltimore.

CASE 1.—A girl of 7 had been successfully treated elsewhere for severe asthma with continuous steroids for eighteen months before her admission to hospital. For the first three months she had been given prednisolone, 12·5 mg. a day followed by 10 mg. a day for nine months. Because she developed a "moon face" triamcinolone was substituted, at first 4 mg. a day and, after three months, 2 mg. daily.

For two months before admission she had experienced intermittent but increasing headache, vomiting, and diplopia. She had a typical "moon face" but no other features of Cushing's syndrome. The striking feature was severe bilateral papillœdema with a retinal hæmorrhage in the right eye. No ocular palsy could be demonstrated and there were no localising neurological signs.

---

[1] Valentine, G. H. *Lancet*, 1959, i, 892.

X-rays of the skull and chest were normal and bone growth was not retarded. Lumbar puncture revealed normal cerebrospinal fluid under a pressure of over 300 mm. A ventriculogram showed normal cerebral ventricles and, in particular, the lateral ventricles did not have the "pinched" appearance sometimes seen in benign intracranial hypertension, nor did there appear to be any increase in the volume of C.S.F. in the subarachnoid space.

Triamcinolone had been discontinued a week before the ventriculogram, and following this investigation she had no further headache, although it had not been influenced by the preceding lumbar puncture. The papillœdema was less severe five days later, and at this time the C.S.F. pressure at lumbar puncture was 170 mm. Three weeks after stopping the steroid the optic discs were normal and she had no symptoms.

CASE 2.—A boy of 8½ had also been successfully treated elsewhere with continuous steroids for severe asthma. For nearly 2½ years he had received daily doses of prednisolone varying from 1.25 to 5 mg. Eleven weeks before his admission to hospital this was replaced by triamcinolone 4 mg. a day because he had developed a "moon face."

He was admitted to hospital with a ten-day history of increasing headache, vomiting, and diplopia, apparently following a blow in the face from a football. He had a pronounced "moon face" but no other features of Cushing's syndrome, the blood-pressure being normal. He had bilateral papillœdema, but no retinal hæmorrhages. Although he habitually closed one eye as if to overcome diplopia, no ocular palsy could be demonstrated and there were no other abnormal signs.

The E.E.G. was normal. A skull X-ray showed slight spreading of the sutures. His height was 48 in. (minus 1 standard deviation from the mean), but his bone age was only 6 to 6½ years and there was slight osteoporosis of the lumbar vertebræ (Dr. C. W. P. Bradfield).

Therapy was changed to prednisolone the day after admission, and reduced gradually until stopped 18 days later. Within eight days of stopping the triamcinolone he no longer complained of double vision and the optic fundi had returned to normal. Lumbar puncture was not carried out at the height of his illness, but a week after admission the C.S.F. was normal and was not under increased pressure. He remained free from symptoms, and subsequent skull X-ray showed that the spreading of the sutures had subsided.

It is likely that the prolonged administration of prednisolone to the second child was the cause of the retarded bone growth. The causal connection between treatment with triamcinolone and the development of raised intracranial pressure can only be presumed, but seems highly probable. The symptoms began respectively 4 months and 2 months after starting such treatment and quickly subsided on withdrawing the steroid. No other cause was found and such rapid recovery would not be expected in the usual case of benign intracranial hypertension. It seems, therefore, that a serious rise in intracranial pressure must be added to the list of toxic effects of triamcinolone. We should also like to emphasise that prolonged steroid therapy, however successful, has peculiar dangers for the growing child.

PRIVATE PATIENTS IN THE NATIONAL SCHEME

SIR,—There are and always will be patients who wish to get the benefits of both "private practice" and National Health Service prescriptions and believe that only a fee will secure their doctor's best attention even when they are registered with him. Such patients regularly offer a cash fee, and as a profession we should face the regrettable fact that there are some doctors who accept such fees. This practice thwarts the efforts of those who carry on their work as faithful servants of their patients fulfilling their Terms of Service. Some N.H.S. practitioners may justifiably not agree with these Terms of Service, but they should not take the law into their own hands.

FORMER LOCUM

SERUM QUININE OXIDASE

SIR,—We read with interest the comments of Mr. Buys Ballot and Mr. Terlingen (March 12) on the determination of "serum quinine oxidase" by the method discussed by Roman and Dulmanis.[1]

We can confirm their observation that in many cases the addition of serum to buffer alone causes a rise in optical density that would be equivalent to an abnormal level of quinine oxidase.

We agree that the rise in optical density is probably due to precipitation of protein under the conditions of the test.

We were in fact led to try the effect of omitting the substrate after finding a raised "quinine-oxidase" level in a series of patients with Sjögren's syndrome, of which hypergammaglobulinæmia is a common feature.

MAGNESIUM DEFICIENCY FOLLOWING MASSIVE INTESTINAL RESECTION

SIR,—The problem of whether magnesium deficiency (or a low serum-magnesium) causes specific clinical symptoms, especially those resulting from disordered neuromuscular function, is once again emphasised by the observations of Dr. Fletcher and his colleagues (March 5).

The difficulty in evaluating the significance of low levels of circulating magnesium as a cause of certain clinical symptoms and physiological abnormalities may be due to the multiple deficiencies generally present in such clinical states and in most animals with experimental magnesium deficiency. Probably for these reasons previous attempts to define a clearcut magnesium deficiency syndrome in clinical medicine have largely failed.

At present we are studying a patient with magnesium deficiency after extensive intestinal resection, in many respects similar to the case described by Dr. Fletcher and his colleagues. In our patient serum-magnesium varied between 0.5 and 0.8 mEq per litre before treatment, and hypocalcæmia and latent tetany were also present. It has been claimed recently[2] that a true magnesium tetany syndrome exists, in which serum-magnesium is low and serum-calcium normal. Administration of 5 g. of calcium gluconate intravenously to our patient, however, resulted in disappearance of the Chvostek and Trousseau signs, associated with an increase in serum-calcium from 6.1 to 8.4 mg. per 100 ml. and a decrease in serum-magnesium from 0.81 to 0.63 mEq per litre, as determined before and 20 minutes after the injection. Magnesium chloride given by mouth led to an increase in serum-magnesium and serum-calcium, and in renal excretion of both, but this treatment has been too short yet to judge the clinical response.

The changes in calcium metabolism after administration of magnesium can hardly be explained as due to an effect on the renal excretory mechanism. The data we have collected so far rather suggest an increased net movement of calcium from intracellular or bone stores to extracellular space. It may be added that large oral supplements of calcium phosphate, as well as intravenous infusions of calcium gluconate for several days, which in normal subjects causes increased magnesium excretion through the kidney, were without significant effect on calcium and magnesium in serum and urine.

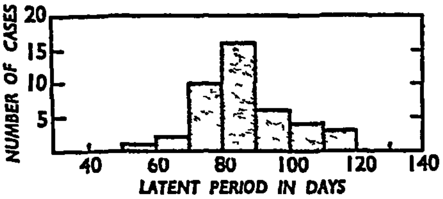
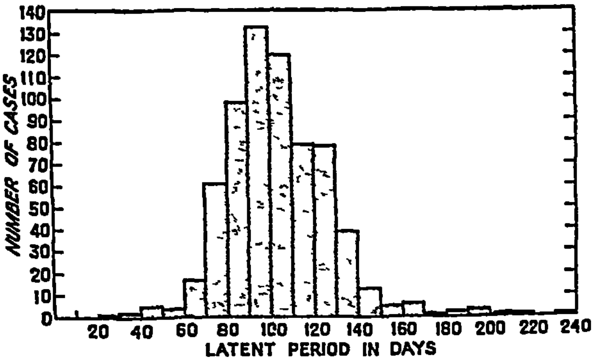
HEPATITIS AFTER INOCULATIONS

SIR,—Your leader of March 5 omits the observations of the late G M Findlay on the incidence of hepatitis after a yellow-fever inoculation

One of the most interesting facets of Findlay's work was that he was able to collect precise information on the latent period from inoculation of the first symptoms in hepatitis in over five hundred cases This may well be a unique experience and worthy of record The accompanying figures are taken from the article by Findlay published in *The Lancet* in 1944 [1]



Latent period in a group of 42 cases inoculated at the same time and place



Latent period from yellow-fever inoculation to first symptoms of hepatitis in 670 cases

HYPOGLYCÆMIA ASSOCIATED WITH SARCOMA

SIR,—We were intrigued to read of Dr Stern's suggestions (March 5) that patients who develop hypoglycæmia in association with certain tumours might be leucine-sensitive individuals in whom the tumour produces enough of this aminoacid to cause hypoglycæmia We have had the opportunity to make a number of observations on a patient with this syndrome

In this patient a test-dose of 10 g of L-leucine given by mouth was followed by a transient small rise in blood-sugar, whereas a similar dose in a leucine-sensitive subject caused the blood-sugar to fall from 59 to 37 mg per 100 ml within 50 minutes [2]

Other observations showed no evidence of an insulin-like effect on the tissue-glucose threshold.[3] Plasma-insulin was within normal limits at a time when the blood-sugar was only 37 mg per 100 ml At operation there was virtually no difference in the glucose levels between blood from an artery and from a vein draining the tumour

The specific activity of plasma-glucose remained unchanged over a period of 60 minutes after the injection of radioactive glucose This means that there was no entry of unlabelled glucose into the blood, and we infer that the hypoglycæmia in this patient with a leiomyosarcoma was caused by the inhibition of hepatic glucose output

Since the removal of the tumour the patient has remained free of hypoglycæmic episodes

A detailed account of this case will be reported elsewhere

PSYCHIATRIC HALFWAY HOSTEL

SIR,—The excellent and critical account (March 12) by Dr Clark and Mr Cooper of the Cambridge experiment with a psychiatric halfway hostel illuminates some of the problems of chronic psychosis

They observed that the passivity of behaviour, so evident in mental-hospital wards, persisted in the hostel until residents realised that they were free from the hospital organisation The close connection with Fulbourn Hospital gave an impression that the hostel was an extension of it, and this required special efforts to overcome Residents did not tend to form social groups or meaningful relationships with one another, yet all were in employment outside According to our own experience at this hospital, these findings were to be expected

Although the ability to work in a particular employment may be as high or higher than in normals, social disability tends to be severe in chronic schizophrenia This is the greatest problem in rehabilitation, yet I believe that it could be prevented to a great extent

The highly artificial, if comfortable and protective, social life of the mental hospital, in which normal motivation disappears, undoubtedly produces an effect, even in the first few days after admission. While this may not be so important in the affective psychoses in which quick or spontaneous recovery is usual, it may be disastrous in schizophrenia

Thought disorder, verbal disability, and psychotic isolation hinder communication and promote the lack of interest patients have for one another For example, two intelligent patients suffering from longstanding schizophrenia shared a room for some years but neither troubled to ascertain the name of the other In contrast, they were both interested in and well informed about members of the staff in whose departments they worked.

In the life of large groups, without responsibility and deprived of the elemental privacies that are characteristic of a normal environment, with continuous exposure to protective mental-hospital routine and the example of others, social sense is stifled and the patient then accepts as his norm the conditions in which he finds himself This seems to be more disabling than prolonged immobilisation after a fracture or illness would be in the functional sense The pattern of the mental hospital, stamped into the patient's mental life during the acute or plastic stages of the illness, plus disuse, may make it impossible for him ever to re-establish himself fully at a normal level The life of the patient after the acute stage has passed is determined mainly by domestic conditions, hospital design, and administrative custom. If these could be altered realistically early enough, social disorientation might be prevented.

An experimental day centre (distinct from the Bristol Day Hospital) for the rehabilitation of chronic psychotics is being developed at Barrow Hospital With the object of breaking the hospital habit, patients initially live, eat, work, and receive psychotherapy during the day at the centre as " internal day patients " They only sleep at the hospital, and are taught to regard it as temporary accommodation necessary for their work and a certain phase of emergence from illness As soon as possible they live at home, to attend as " external day patients " by ordinary public transport or picking up the hospital coach Some travel more than 12 miles and are rarely late

---

[1] *Lancet*, 1944 ii, 302

[2] Butterfield, W J H, Whichelow, M J, Wright, P H, Woolf, L I *Nature Lond* (in the press)

[3] Butterfield, W J H, Holling, H E *Clin Sci* 1959, 18, 147

It is hoped to find places for these patients in industry, and the recently formed company—I T O —in Bristol will be invaluable

The possibility of treating acute cases of schizophrenia, even during the first week in hospital, at the centre is being explored

It appears that

(1) Schizophrenic patients learn from normals by contact and example but not from one another Living amongst normals promotes normal values

(2) Occupation must be gainful, with remuneration according to effort

(3) The integration of patients in small numbers with normals, at work and outside, is to be aimed at Even travelling by public transport to work is appreciated as being a procedure involving normal people and normal habits

(4) The response of any patient to rehabilitative measures cannot be predicted, for even longstanding cases may suddenly show a remarkable social recovery Much research remains to be done in motivation and allied problems

(5) The application of the day system early may prevent chronic social disability

(6) Boarding-out or lodging homeless single patients with interested families is the ideal

(7) A halfway house or hostel should be situated well away from the hospital and organised on non-hospital lines

Although the importance of social rehabilitation of psychotics is widely recognised, the fringe of the problem has hardly been touched Adequate funds to provide something like conditions of a normal social life, with sufficient staff to treat patients in small groups and revision of old-fashioned concepts of the needs of the psychiatric hospital, are a prime necessity For, in spite of all our efforts, only a small proportion of young and recent patients with schizophrenia are discharged from treatment without some semipermanent social disability

Barrow Hospital, Bristol **R E HEMPHILL**

DISORDERS OF "PERSONAL TIME" SENSE

SIR,—Dr Gooddy [1] drew attention to the ways in which disorders of "personal time" sense may be provoked We can confirm that even normal persons may under stress exhibit gross disorders of this nature with possible far-reaching practical implications

Towards the end of a series of experiments designed to study the effects of high temperatures on Service personnel in Singapore a number of volunteers were exposed at rest to a very warm and humid atmosphere until they either collapsed or were on the verge of collapse The following abstract from an unpublished report [2] gives some indication of the type of disorder in "personal time" which was observed

> "As time went on the subjects, and at times the observers, became poorly orientated in time and accused the technicians in the air-conditioned observation chamber incorrectly of not making measurements at the correct time and of not bringing drinking water as quickly as they might Time passed very slowly and the measurement of skin temperatures seemed to be a never-ending procedure The subjects mistook the observers' names, used the wrong words when they spoke and slurred their words, they became either euphoric and talkative or morose, irritable, and suspicious, and these attitudes sometimes alternated during the same experiment The writing on their note pads became larger, less distinct, and less intelligible until this duty had to be turned over to a technician One of them repeatedly insisted that he was clear-headed and quite fit whilst he was mistaking the names of the observers whom he knew well and thought the time was an hour later than it was although he was looking straight at a clock only a few feet away These mental aberrations, associated with some cyanosis and temporal and circumoral pallor on using the facial muscles, were very suggestive of cerebral anoxia"

Thus, not only may "personal time" sense be impaired, but the person affected may be euphoric and overconfident or, alternatively, morose and irritable, and this combination of symptoms may occur some time before he succumbs to heat stress This underlines the importance of keeping those who have the work at very high temperatures under strict observation by an observer who is not himself in a position to be equally affected by heat stress, and ensuring wherever possible that men with significant responsibilities are not exposed to conditions which may render them grossly incompetent

THE CARPAL-TUNNEL SYNDROME

SIR,—I was most interested in the papers by Dr Wilkinson and Dr Foster on the carpal-tunnel syndrome (Feb 27) and the methods of treatment recommended I should like, however, to make some observations before this condition is accepted as a clinical entity

The proportion of patients attending clinics and complaining of these symptoms appears to be increasing and they are often associated with rheumatic manifestations in other parts of the body In my experience, in the great majority of cases, these symptoms are caused by "myalgic areas or spots" in the muscles of the shoulder girdle referring pain, spasm, and other signs of acroparæsthesia to the wrist, hand, and fingers [1]

Deep pressure over these spots will accentuate the symptoms, and injection of 2% procaine into them will often relieve the pain almost at once Symptoms are worse at night in bed because of the continuous body pressure on the spots

These spots may originally have been due to repeated trauma and may have remained quiescent for long periods until they were triggered off by some exciting factor, such as strap-hanging in tubes and buses, carrying heavy packages, or a strain or a fall Having treated very many patients on these lines I find it is usual to discharge them symptom-free within three weeks, and there are very few recurrences

In my view, therefore, surgical interference or other local treatment is not essential and should only be used in the absence of myalgic spots in the shoulder girdle

London, W 1 **LOUIS MOSS**

LEAF PROTEIN AS HUMAN FOOD

SIR,—Mr Pirie's article [2] refers to the possibility of the production of leaf protein for human consumption, particularly in areas "where the need is most acute" As a matter of fact, during the famine in Bengal in 1943, protein material was extracted in this laboratory from grass, water hyacinth, and certain other waste leaves and fed to people in the form of some familiar Indian preparations It was well received Since then leaves of a number of other species of plants including those of jute, sugar-cane, maize, cassava, and banana, which might be obtained as rejection from plantations, were examined More recently leaves of leguminous plants, which contain 27–35% protein on the dry basis have been investigated [3] Some of the results obtained will be published elsewhere in detail

The industrial production of leaf protein is desirable In undernourished countries of the world, however, the larger body of the population lives in villages A domestic method which has been developed is that of macerating crushed green leaves with 2% sodium carbonate solution, straining the extract through cloth, slightly acidifying it with lemon juice or tamarind juice, and warming, when the protein material is precipitated *This is filtered through cloth giving a green protein material with a leafy flavour* The colour and flavour,

however, do not matter if the fresh protein material is incorporated in common Indian dishes like curries, "pakora" (a fried "snack" with vegetables), and "puries" (fried thin slabs of wheat flour dough). By the above method of extraction about 60% of the leaf protein is obtained, the rest remaining in the residue, which can be fed to cattle, as they need protein also. This method has been actually practised in the home and found satisfactory.

This method has also been used on a fairly large scale for the extraction of protein from leaves of grass, water hyacinth, gliricidia, ramie, and drumstick, by using conventional equipments. The protein materials so obtained have been exhibited in the pavilion of the Ministry of Food and Agriculture of the Government of India in the World Agricultural Fair which opened in New Delhi in December, 1959. Indian food preparations incorporating these protein materials were made and were well received by visitors. It would appear therefore that there is considerable possibility of the development of leaf-protein food on both domestic and industrial scales.

TREATMENT OF HÆMANGIOMATA AND INFANTILE SCOLIOSIS

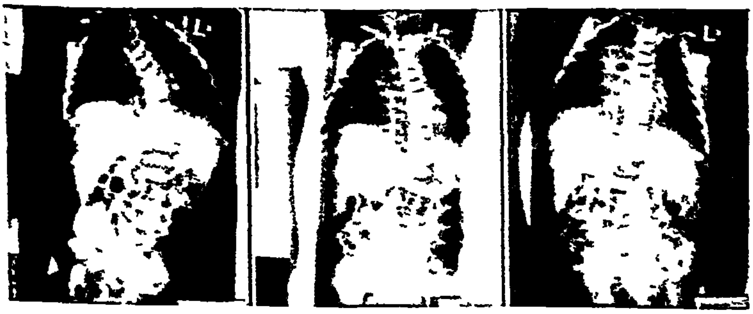
SIR,—There is a curious likeness between the two controversies, on hæmangiomata and infantile scoliosis, which I have deliberately stirred up in your journal recently, with the object of questioning the present teaching that both conditions should be studied but not treated.

I cannot say that I am impressed by this "study" and it embarrasses me to think what a trained biologist would think of it. Consider:

(1) Both conditions are progressive, yet in neither is there an attempt to identify the earliest stage of this progress, while regarding angiomata there is considerable disingenuousness about the disfigurements left by the final stage. The series of photographs shown by Dr Russell (Jan. 30) illustrates this, the angioma is first shown growing rapidly at the age of two months, what was it like two months earlier?

(2) Mr Scott (Feb. 27) states that 80% of babies have scoliosis at six months, the condition gradually becoming less common till none are affected at two years. As this opinion is based on the X-rays of 75 children who were not themselves examined, it seems to me that all he has discovered is that 80% of young babies squirm when held down on a hard X-ray table, and that as they grow older they squirm less. James[1] quotes this curious result of "study" as showing that scoliosis is very common in infants, though in my experience it is very rare, occurring as far as I can make out once in many thousand births.

As to X-ray evidence, I think far the best and the only reliable one is what I call a "triptych". In the accompanying example the centre picture shows the relaxed position, flanked by records of the full lateral range of movement to either side. This is a typical example, from a baby with a typical history. His mother noticed a crooked back at five weeks; she was given the usual advice by her general practitioner. After another five months had been wasted the deformity was so obviously worsening that it was sent to me. The radiologist reported that the triptych showed no fixed scoliosis, whereas I consider it a classical example of this, the curve increasing on bending in one direction, and not entirely disappearing when bent in the other. After splinting and physiotherapy the child is now, at three years, clinically normal.



(3) Surely an important part of the study of surgical conditions is that of the effect of treatment on them. I cannot see the sense of deferring treatment till we understand the ætiology; supposing we never agree on this, do we never try treatment?

(4) As to the ætiology I have a simple explanation of this, at present barred by the orthodox orthopædic ban on discussing intrauterine conditions. James[1] argues that I cannot be right in considering it due to malposition in utero, since in only two of his cases was it present at birth. The neglect to distinguish between being present and being noticed deprives this of all meaning.

(5) In both instances I am challenged to provide evidence that is obviously impossible to obtain, since it involves knowing what would have happened had nothing been done. Any good results obtained by treatment will meet the criticism that the condition would have cured itself anyway.

(6) Finally I submit to my colleagues the opinion that in the sight of Heaven one is not justified in withholding treatment from a group of ill-understood cases on the grounds that some, nobody knows which, will get better spontaneously.

London, W.1
DENIS BROWNE.

"CRISIS IN NURSING"

SIR,—The suggestion by Mr Atkins (March 12) that the training of theatre nurses be divorced from that of ward nurses did not appeal at all to the nurses to whom I showed his letter. "The cool hand on the fevered brow" concept of nursing has long since passed, and nowadays girls enter the profession because it is an eminently worthwhile career offering reasonable prospects, a measure of responsibility, and variety of experience; it is this variety which is particularly attractive in view of the tedium of so many careers open to girls of this age.

If the profession can only offer potential recruits either pure ward nursing or pure theatre nursing it will be in danger of losing the valuable type of girl who has both character and resource and who, by her very nature, could not give of her best in a monotonous job.

While the theatre nurse would not suffer from lack of experience in the wards, the ward nurse would surely feel the lack of theatre experience very keenly, particularly when working on surgical wards. Her effectiveness in reassuring the patient about to go for operation would be seriously impaired if it was as much a mystery to her as to her patient, and can she really be so concerned about postoperative progress if the surgical proceedings are, at best, learnt second-hand from a textbook?

Specialisation has surely gone far enough in the nursing profession. Let us continue to give a varied basic training to produce nurses, and not merely theatre technicians, or ward orderlies.

Bristol.
GEOFFREY H. ROBB.

SIR,—Does Mr Atkins realise that throughout their training nurses are repeatedly "drafted from the wards", to casualty, outpatients, diet kitchens, and from medical to surgical wards, as well as to theatres?

Remembering the apprehension with which I viewed my first visit to the theatre, accompanying a patient from the surgical ward, I cannot imagine many young people wishing to do theatre work, and theatre work only, without some initial introduction

---

[1] James, J. I. P. Modern Trends in Diseases of the Vertebral Column. Edited by R. Nassim and Jackson Burrows. London, 1959.

Now that there is so much mechanisation in theatres I can see the need for a theatre technician Does Mr Atkins suggest that an apprenticeship as an electrician, or a fitter, might be a better preparation than the drudgery of sluices and bedpans Would the technicians assist at operations too?

How will nurses in training ever discover whether they have the temperament peculiarly fitted to theatre work? Many find out only after practical experience on both wards and theatres

CEREBRAL ANGIOGRAPHY IN THE DIAGNOSIS OF THE ACUTE STROKE

SIR,—The article by Dr Bull and his colleagues in your issue of March 12 is a most useful contribution to the knowledge of this interesting and topical subject In the South-Western region we have recently surveyed 100 consecutive cases of "stroke syndrome", this term being used to describe cases with a presenting symptom of unilateral weakness or paralysis of sudden or recent onset, and cases were not excluded because subsequent finding showed a lesion other than a vascular one Apart from the difference in the rapidity of onset, there was a close similarity in the clinical histories of these patients, and cerebral angiography had been requested as an aid to diagnosis One of the main objects of the survey was to attempt to assess the frequency of carotid-artery disease, for it is well recognised that diagnosis in the pre-hemiplegic phase is most important if there is to be a chance of successful treatment We found complete occlusion in 13 cases and partial occlusion in a further 4 This is in general agreement with Dr Bull's findings and also with those of Tatelman[1] in Detroit, who analysed 200 consecutive cases of "strokes" referred to a cerebrovascular unit.

It is most important to assess this frequency in the light of the present accepted knowledge that half to two-thirds of cases of complete occlusion have a premonitory history, often long drawn-out, of unilateral symptoms before the onset of the final episode Thus Luessenhop,[2] in a survey of the world's literature, covering 486 cases, found that only 108 cases had an acute onset of less than forty-eight hours, the majority extended over weeks or even months 1 of our patients with carotid stenosis had in fact a history of six months' weakness and stiffness of the joints of the hand, for which he had been originally referred to the orthopædic department. Carotid angiography revealed the stricture and thrombo-endarterectomy resulted in complete relief of symptoms

In those cases with a subacute onset there were a number of tumours both of glial and meningeal origin, subdural hæmatomata, and also unsuspected intracerebral abscesses Amongst those with an acute onset were cases of arteriovenous malformation, 2 of which had bled for the first time in subjects over the age of 55 years, and a remarkable case of a meningioma in a man who had been confined to bed hemiplegic for four years following an acute "stroke" Removal of the tumour resulted in his being able to walk again.

One of the main conclusions of our survey was that 10–15% of cases presenting in this category of "stroke syndrome" were likely to have underlying operable conditions It would therefore seem rewarding to investigate more frequently those cases with a progressive or recurrent unilateral history, in the hope of discovering those conditions which are amenable to treatment, and particularly of forestalling those which at the moment proceed to complete occlusion of the carotid artery

Frenchay Hospital,
Bristol J L G THOMSON

SIR,—In their informative paper, Dr Bull and his colleagues point out that cerebral vessels may be displaced by the œdema of infarction as well as by intracerebral hæmorrhage Great difficulty may arise in this differential diagnosis even where a subarachnoid hæmorrhage has clearly taken place as shown by the presence of blood in the cerebrospinal fluid The occurrence of quite large cerebral infarcts is now a well-recognised complication of subarachnoid hæmorrhage, and, although displacement of cerebral vessels in the presence of subarachnoid hæmorrhage usually denotes an intracerebral hæmatoma, it may be the result of infarction

I recently saw a young man who had undergone clipping of the right anterior cerebral artery for aneurysm eighteen months previously He was admitted with subarachnoid hæmorrhage, and angiography showed that the wire clip had come off the artery (which was patent) Displacement of the anterior cerebral arteries to the left was wrongly assumed to be due to a hæmatoma, and craniotomy revealed only infarction of the frontal lobe Aspiration by means of a burr-hole and cannula would probably have saved a needless major operation, and I would suggest that this simple procedure should be an invariable preliminary to craniotomy in these cases (unless, of course, an open operation is to be performed anyway for a direct attack on an aneurysm or angioma)

Middlesbrough, Yorks P R R CLARKE

THE ROYAL COMMISSION AND TIME-EXPIRED SENIOR REGISTRARS

SIR,—On p 91 of the report of the Royal Commission on doctors' and dentists' remuneration we read that "In mid-1959 there were at least 141 senior registrars who had completed training and were awaiting higher posts"

One of the reasons most frequently given by regional hospital boards for not increasing the number of new consultants in their areas is lack of money Thus the recommendation of the Royal Commission that there should be a new category of 100 A-plus distinction awards of £4000 each for consultants, in addition to existing awards, must come as a bitter blow to those of us who are in our sixth (and even later) year of training and waiting Indeed several of us have attained additional qualifications such as the CH M or M.D by thesis, and even Hunterian professorships—achievements which are no doubt often noted by Lord Moran and his colleagues when granting distinction awards at present

I should like to suggest that no A-plus distinction award should be offered by the Government or accepted by members of our profession until *all* the time-expired senior registrars have been granted consultant status Such a gesture on the part of the Government and our seniors would do much to reduce the bitterness and frustration in the hospital service

TIME-EXPIRED SENIOR REGISTRAR.

⁂ The A-plus awards cannot fairly be dissociated from the other recommendations of the Royal Commission As a whole, these recommendations would raise the remuneration of all consultants, and increase its range, while reducing the proportion who get more than basic rates Our correspondent is presumably objecting to the increase of *range* Though, like him, we deplore the failure of the N H S to provide, in some *places*, enough consultants for the work in hand, and its failure to give suitable posts to some of those it has trained, we do not think that in their present form his proposals would do much to help The cost of improving the service by creating new consultant appointments can be

---

1 Tatelman, M *Radiology*, 1958, 70 801
2 Luessenhop, A J *J Neurosurg* 1959, 16, 705

quite substantial when they involve giving the new consultant new staff With surtax as it stands, the amount the Treasury would save by paying a hundred consultants £3000 rather than £4000 would not suffice to influence the Government's policy towards new posts —ED L

LUNG CANCER AND TOBACCO MOSAIC VIRUS

SIR,—There is no need to discuss again the improbability of the suggestion [1] that tobacco mosaic virus may be a cause of lung cancer, because it has already been commented on [2] But one point in the revival of the idea by Dr Bothwell (March 19) should be quickly contradicted There is nothing peculiar in the smokers' relationship to the swallowed decomposition products of R.N.A. from the T M V in a cigarette. There are many other sources of heated R.N.A. Steak cooked in the English style—i e., singed on the outside and raw in the middle —contains the whole gamut of products of pyrolysis of R.N.A

Two assumptions would have to be made to give the suggestion any a-priori probability that the effective agent is volatile, and that some special component is present in T.M.V but absent from other forms of R.N.A.—e g , that from healthy tobacco leaves and edible parts of animals and other plants besides tobacco There is no evidence for either assumption. Obviously the absence of evidence does not constitute disproof, and it may be worth comparing the effects of tobacco from infected and uninfected plants Anyone doing this should however remember that virus infection leads to many chemical changes in the host besides the multiplication of the virus Any one of these changes could explain a correlation—if one should be found.

SOME UNCRITICISED ASSUMPTIONS IN PSYCHIATRIC THOUGHT

SIR,—Psychiatric treatment will remain largely a matter of conflicting opinions, at least until more is known When psychiatrists set up their opinions against each other, judgment is more a matter of legal logic than reliance upon the treasured " scientific verifiability "

A psychiatrist should first reveal his bias (system of opinions) whenever he ventures to speak. Mine coincide with those of Dr McConaghy (March 19) in critical unrest about Freudian psychotherapy, deviate sharply away as regards the use of the organic analogy

Should we be unduly sensitive or irritable if query is turned on the reasons for all our divergences, or if somebody wants to query staff mentality as well as patient mentality? Or is " mentality " likely to become a bad psychiatric word, bearing as it does metaphysical and unphysiological odours?

Meanwhile, some psychiatric patients continue to get well and others do not—all subjected to a variety of processes physical, chemical, and, for the present at least, psychological Perhaps it is fortunate that our patients are independent of our conflicts, perhaps our patients are under the patronage of some dialectical deity And perhaps we must look for more knowledge about psychiatry in a dimension which is not confined to our favoured categories—what has been called the hoped-for Einsteinian revolution in psychiatry Einstein included observer-bias and subjectivity in his theories

And why do critics of psychology and psychotherapy in psychiatry always treat the subject superficially? Perhaps this is the cause of the criticism and the rejection—namely, the failure to understand, which underlies all human problematics, including our psychiatric patients And I fail to understand Dr McConaghy's distinction between the psychiatrically ill and the neurotic.

The tendency to regard psychiatry as primarily a physical matter on a par with general medicine and to minimise psychodynamics may arise out of the inability to provide psychotherapy, owing to lack of time or disinclination or overcrowded psychiatric practice, or other similar reasons The temptation to make a virtue out of such necessity should be resisted If we have not the time for psychotherapy and psychodynamics let us say so, instead of suggesting that it is because psychiatric patients are fundamentally or predominantly organic problems

St George's Hospital,
Stafford

H M FLANAGAN

HISTORY AND THE PARASTERNAL LYMPH-GLANDS

SIR,—Your annotation of March 19 has made charming reference to the work of my father and me. At the risk of seeming churlish and pedantic, I must nevertheless point out that Dr W S Halsted's remarks in 1898 [1] were not " the first known record of interest in the spread to the internal mammary lymph-glands of cancer from the breast." What is probably the first reference to this matter reads as follows " The case is equally or perhaps more hopeless, if the mammary absorbents have carried the poison to glands within the chest, out of the reach of surgery, the patient then must die "

To continue the mode of your annotation, it seems likely that even the question-master would not have placed this quotation. It was written by W C. Cruikshank in 1790 in the second edition of his book *The Anatomy of the Absorbing Vessels of the Human Body* [2] Cruikshank was the probable discoverer of the internal mammary lymph-nodes (the Italians favouring Mascagni) and the context of the passage quoted leaves no doubt that he was referring to these nodes and the spread of cancerous " poison " to them. In 1805 Sir Everard Home, in his *Observations on Cancer connected with Histories of the Disease*,[3] described a case in which breast cancer had metastasised solely to the internal mammary chain, and expressed his belief that " when it takes such a course the lungs are liable to be affected by it." I know of two other plain references to invasion of the parasternal lymphatics before Halsted's paper was published.

You have commented on the therapeutic problem posed by invasion of the parasternal lymph-nodes in breast cancer May I concur with your remarks and add some personal comments? Neither the surgical excision nor the radiotherapy of these nodes has yet had time to prove its usefulness In some quarters there has been loud condemnation of extended radical mastectomy because of the added mutilation it involves This is the wrong reason for condemnation, because extended radical mastectomy adds little to the hateful deformity produced by even a simple mastectomy It is on results that judgment must be based, and it must be admitted that so far only the technique described by Urban [4] seems to offer promise. I have abandoned the extended mastectomy technique which Patey, Hand, and I described in your columns,[5] because its early results do not show any improvement over less drastic operations It is my personal view that irradiation will displace surgery for treating the internal mammary chain, and it is encouraging to know of Smithers and Rigby-Jones' new technique because hitherto irradiation has shown no more notable achievement than surgery in coping with internal mammary deposits In the first serious and sustained attempt ever made to deal with parasternal deposits, my father used irradiation by implanting radium tubes in the intercostal spaces after he had completed a radical mastectomy His brilliant conception did not yield the results which it deserved to show. Nor has conventional radiotherapy with the 200-kilovolt machine been any more successful in producing histological "sterilisation" of parasternal lymph-nodes than it is with axillary lymph-nodes, as I have seen by doing biopsies of the parasternal nodes after completion of a course of radiotherapy.

John Hunter said "Don't think—try the experiment." The experiment of treating deposits of breast cancer in the parasternal nodes needs time and detached observation, not hasty judgments.

The Middlesex Hospital, London, W.1. RICHARD HANDLEY

BRETYLIUM TOSYLATE IN THE TREATMENT OF HYPERTENSION

SIR,—Dr. Lowe and Professor Rosenheim (March 19) report exertional hypotension in patients receiving bretylium.

In the 13 patients whose blood-pressure was recorded before and after exertion, readings taken during exertion would have been of great interest. This can be done with the patient exercising on an ergometer.

We have shown[1] that in mild hypertension a rise of blood-pressure occurred during exertion which was more pronounced than in normal persons. Hexamethonium depressed not only the resting blood-pressure but the peak blood-pressure during exercise. In severe hypertension, a fall in blood-pressure may occur during exertion with a post-exertional rise. Hexamethonium did not cause an alteration in the pattern of blood-pressure changes during exercise. However, after exertion a marked fall of blood-pressure sometimes occurred. This post-exertional fall in blood-pressure was not related to treatment.

In the group of patients receiving bretylium with symptoms on exertion described by Dr. Lowe and Professor Rosenheim, one would like to know not only the blood-pressure changes during exercise while under the influence of bretylium but also the changes during exercise when untreated.

London, W.1. P. B. S. FOWLER

CATHETER DRAINAGE AND INFECTION IN ACUTE RETENTION OF URINE

SIR,—Dr. Steele (March 5) has already referred to the catheters which I have devised for use after prostatectomy and bladder operations in general. These catheters will be described in more detail elsewhere, but in view of the recent correspondence, it is worth noting that they have been in use in the department of urology at Jervis Street Hospital, Dublin, for almost two years and have proved very satisfactory.

The catheters are made on the Gibbon pattern, and of the same material (P.C.V.) but they are whistle-tipped and size 18F. Because of their thin but adequately rigid wall and the consequent high ratio of bore to external diameter, larger sizes have not been found necessary. Two different modifications are available: (a) a sliding flange catheter which allows the length of catheter in the urethra and bladder to be adjusted to the patient's requirements, and (b) an irrigating pattern with a small external side tube for continuous irrigation: in this second variety the flange is fixed as in the original Gibbon catheter. The distal end of the catheter is adapted to fit a standard Lane bottle to provide closed drainage.

We have found postoperative blockage much less frequent with these catheters than with other varieties. Because of the length of the catheter, when washouts are necessary they can be performed with much less mess and with far greater attention to asepsis than in the case of catheters of standard length. The catheters are sterilised by autoclaving and can be used repeatedly. They are readily available from Messrs. Portland Plastics.

Parliament

Filling a Practice Vacancy

IN a debate on the adjournment on March 14 Mr. HORACE KING, PH.D., suggested that there was often unnecessary delay in filling a practice vacancy because the executive council's selection had to be confirmed by the Medical Practices Committee and because candidates then had the right of appeal to the Minister. This procedure could cause a delay of six months during which it was difficult to hold the practice together. Local executive councils resented suggestions that they might be susceptible to improper influences. They suggested that they should be allowed to make these appointments subject only to the check of an appeal to the Medical Practices Committee. Appeals, they proposed, should be restricted to candidates on the short list.

Miss EDITH PITT, parliamentary secretary to the Ministry of Health, pointed out that only a few vacancies were filled by this procedure, which was not used for partners or assistants. Last year, for instance, only 168 doctors were appointed to advertised single-handed vacancies, whereas 900 were admitted to the medical list in other ways. In 1959 the average number of applications for these vacancies was 24, but for vacancies with substantial lists in the South of England competition was keen and 99 doctors had applied for a vacancy in Hove. Where there were so many applications, many well-qualified applicants were inevitably excluded from the short list. But for the knowledge that their claims were reviewed by an impartial body such as the Medical Practices Committee, there might well be more time-consuming appeals. As it was, the average time taken to fill a vacancy—57 days in England and Wales and 60 days in Scotland—was well within the three months' notice required of a doctor retiring from the National Health Service.

QUESTION TIME

Control of Drugs

Mr. SYDNEY IRVING asked the Home Secretary if he would state the date from which the ban on the sale of 'Preludin' and the twenty other substances listed by the Poisons Board except by medical prescriptions would become effective.—Mr. R. A. BUTLER replied: After considering representations, I have decided to ask the Poisons Board to reconsider the scope of its recommendation with respect to guaiphenesin. My information is that this substance is not at present available in this country in any preparation that is liable to abuse. I have also decided that no further control is necessary in respect of nialamide, which is already subject, under the Therapeutic Substances Act, 1956, to substantially the same degree of control as that recommended by the Poisons Board. With these exceptions, I hope to put into effect, from the beginning of next month, the recommendation of the Poisons Board relating to the substances mentioned in my answer on Feb. 11.[1]

'Imferon'

Lord BALNIEL asked the Minister of Health, in view of the doubts which have arisen regarding the safety of this drug, whether he would ensure that it is not included in *Prescribers' Notes* until further tests have been undertaken.—Mr. DEREK WALKER-SMITH replied: The manufacturers have now informed me that they have decided to suspend the sale of this drug for general use pending an independent re-examination of all the available evidence.

Juvenile Courts in Hospitals

Dr. DONALD JOHNSON asked the Minister under what authority the Sheffield Regional Hospital Board was approaching magistrates with a view to establishing special juvenile courts in hospitals to intervene if parents refuse permission for an operation on a child, and what plans he had for establishing similar courts in hospitals in other regions.—Mr. DEREK WALKER-SMITH replied: The Sheffield Regional Hospital Board is seeking to ensure only that the existing provisions of the Children and Young Persons Act, 1933, should, if invoked in an emergency, operate speedily. The board does not need any specific authority for this, and any similar action elsewhere would be a matter for the hospital authorities concerned.

---

[1] See *Lancet*, Feb. 20, 1960, p. 446.

Home Nursing Service in London

Mr ROBERT JENKINS asked the Minister whether he had now reached a decision on the London County Council's proposal to take over the home nursing service.—Mr WALKER-SMITH replied: I have informed the Council that I consider that the right course is to defer any decision until the report of the Royal Commission on Local Government in Greater London has been received and considered.

Brain-washing

Mrs BARBARA CASTLE asked the Minister of Health to what extent National Health Service psychiatrists were made available to the Services, the police, or the security authorities, for interrogation or brain-washing.—Mr WALKER-SMITH replied: No such arrangements have ever been made. Mrs CASTLE: Is the Minister aware that Dr Kennedy, who does National Health Service work, has declared that he has no complaint against the content of the report of his speech in the *Observer*, in which he stated that a technique of brain-washing was developed in Britain during the war and was used to extract confessions?—Mr WALKER-SMITH: It is quite clear what Professor Kennedy did not say. He did not say that these techniques had ever been used in this country. In fact, the material contained in Professor Kennedy's discourse had been previously published in journals available in this country, and perhaps, if the hon. Lady has not already done so, she could study the article in the *Archives of Neurology and Psychiatry* for August, 1956.

National Health Service Expenditure

Lord BALNIEL asked the Minister the gross cost of the whole of the National Health Service for Great Britain as a percentage of the gross national product in 1949, 1951, and in each subsequent year.—Mr WALKER-SMITH replied: The figures[1] are as follows:

	%		%		%
1949	3·7	1953	3·4	1956	3·3
1951	3·5	1954	3·3	1957	3·3
1952	3·6	1955	3·3	1958	3·4

A firm figure for 1959 is not yet available, but such estimates as can at present be made indicate that it may be about 3·6%.

Manslaughter Sentences

Dr DONALD JOHNSON asked the Home Secretary whether he was aware that Michael Dowdall, who was recently tried on a charge of murder at the Old Bailey and found not guilty on a successful defence of diminished responsibility,[2] was sentenced to life imprisonment for manslaughter, and that there was consequent anxiety that, by virtue of the usual remissions to such a sentence, this man would be freed after a term of years; and whether he would make a statement of policy in regard to remission of sentences of imprisonment imposed under the provisions of section 2 of the Homicide Act.—Mr R. A. BUTLER replied: Persons sentenced to imprisonment for manslaughter under section 2 of the Homicide Act are in the same position as those sentenced for any other form of manslaughter. If the sentence is a determinate one the prisoner may earn remission, but if it is a sentence of life imprisonment there is no remission and it rests with the Secretary of State to decide when to discharge the prisoner on licence. In considering when any prisoner sentenced to life imprisonment can be discharged the Secretary of State takes into account, among other factors, the question whether the prisoner is likely to be a danger to the public, and particular attention will be paid to this point in dealing with prisoners whose responsibility for their offence has been found to be diminished.

Children on Remand

Mr A. G. BROWN asked the Home Secretary how many children under 16 years of age were remanded to Holloway Prison, instead of being sent to remand homes, during January, 1960.—Mr DENNIS VOSPER replied: Two. Mr BROWN: Is the Minister aware that the measure of public concern over such imprisonment of children is reflected in the widespread publicity the national Press has afforded the alarming disclosure, by a recently discharged prisoner, that a little girl of 14, guilty of a breach of probation in that she played truant from school, is incarcerated in a ward of Holloway Prison hospital and is in the company of adult prisoners awaiting trial on such grave charges as murder and attempted murder? Mr VOSPER: I share the concern about this particular case, which is additional to the two to which I referred in my answer. The juvenile court concerned acted quite properly under section 27 of the Criminal Justice Act, 1948, and this child was committed to Holloway as there was no place available at a classifying school. I have investigated the matter and a place has been found for this girl in an approved school to which she is being sent.

88-hour Fortnight for Nurses

By Oct. 31, 1959, the 88-hour fortnight had been introduced in full or substantially by 87%, partially by 11%, and not at all or negligibly by 2% of the general hospital groups. Corresponding percentages for mental and mental-deficiency hospital groups are 91%, 5%, and 4% respectively, and for teaching hospitals 66%, 17%, and 17%. The Minister of Health has told hospital authorities that he expects them to complete the introduction of the 88-hour fortnight in the next financial year.

Public Health

Mental Health Statistics

THE Supplement on Mental Health to the Registrar General's Statistical Review of England and Wales for the three years 1954–56[3] contains detailed statistical tables with a brief commentary on the more important items.

Populations of mental hospitals.—Although the numbers of admissions to and discharges from mental hospitals continued to increase year by year, the numbers of patients resident at the end of each year decreased from 148,080 in 1954 to 145,593 in 1956.

Admissions to mental hospitals.—There were 83,994 admissions in 1956, of which first admissions numbered 47,413 (56%). First admissions in 1956 exceeded those for 1951 by 23% for males and 22% for females, and admissions for a second or subsequent visit were 75% higher for males and 79% higher for females. By 1956 the proportion of voluntary patients among first admissions had reached 78%.

Admissions to mental hospitals according to area of residence.—An analysis of first admissions by type of area of residence of patients shows that, for psychoses of all forms together, people living in rural areas had the lowest rates and those living in the conurbations the next lowest; the highest admission-rates occurred in people living in urban areas with populations under 100,000.

Admission-rates by social class for males aged 20 and over.—Both first-admission and readmission rates were lowest in 1956 in social class II (managerial occupations) and highest among unskilled workers of social class V.

Admissions and discharges for mental-deficiency hospitals.—Admissions and discharges have fluctuated from year to year, but the numbers resident increased from 55,048 in 1951 to 58,799 in 1955, dropping to 58,334 in 1956; this decrease was chiefly due to the discharge of 2406 patients from licence in 1956, compared with 1058 in 1955.

Statistics for Scotland in 1958

In 1958 Scotland's birth-rate was 19·25 per 1000 of the population[4]; this was the highest since 1930, apart from the post-war years. The death-rate rose from 11·9 in 1957 to 12·0 in 1958. Infant mortality amounted to 27·7 per 1000 live births; this is the lowest rate ever recorded in Scotland.

---

[1] The gross national product has been taken at market prices. The cost of the N.H.S. has been taken as total expenditure met from all sources of revenue. The figures have been interpolated from those for financial years.

Obituary

JOHN CONSTABLE BROOM

OBE, MD St And

Dr J C Broom, bacteriologist in the Wellcome Laboratories of Tropical Medicine, London, died on March 16 He was 57 years of age

He was born in Leuchars, Fife, the son of the Rev William Broom He was educated at Madras College, St Andrews, and at St Andrews University, where he graduated M B in 1924 His resident appointments were in the North Lonsdale Hospital, Barrow-in-Furness, and in the Murray Royal Asylum, Perth In 1929 he took the M D and was awarded the Rutherford medal for his thesis

In 1928 he began his life work as a research bacteriologist in the Wellcome Bureau of Scientific Research, Euston Road, which later became known as the Wellcome Laboratories of Tropical Medicine For the first fifteen years or so he had as his senior colleague the late Major H C Brown, and together they published between 1929 and 1937 a series of valuable studies of the part played by the electric charge in relation to bacteria, protozoa, and the antigen-antibody reactions

In this work on cataphoresis they showed variations in the migration of different strains of typhoid-salmonella species in the electric field, alterations in the sign of the electric charge of the trypanosomes which reappear after spontaneous cure of laboratory animals, and the alterations in complement fixation, hæmolysis, and bacterial phagocytosis that depend on changes of electric field In some of the work on trypanosomes they collaborated with Dr C A Hoare, F R S Broom also worked with the late Dr G M Findlay on Rift Valley fever and yellow fever During the late war, Broom took the main responsibility for the work of inoculation against yellow fever at the Wellcome Laboratories, and for this he was appointed O B E in 1946

Several years before the war he had joined in H C Brown's work on leptospirosis, and from 1939 it became more and more his main subject of study Since the war he has been the leading worker in this field in Great Britain and one of the group of eminent international students of leptospiral diseases He made his laboratory a centre of help, advice, and collaboration for workers in many countries where the incidence of leptospirosis has lately been found to be greater than was known

From 1951 he was secretary of the leptospira subcommittee of the International Committee on Bacteriological Nomenclature His twenty or more publications on the subject included a most useful system of classification of leptospires (with Prof J W Wolff, of Amsterdam), surveys of the disease in man and rodents in Great Britain, participation in an international symposium in Washington in 1952, and a monograph (with Dr J M Alston) on *Leptospirosis in Man and Animals* (1958) Broom gave the Milroy lectures at the Royal College of Physicians of London in 1952 He has been honorary treasurer of the Royal Society of Tropical Medicine and Hygiene since 1947

Recalling Broom's early days at the Wellcome Bureau, J M A writes

" He and Brown were a contrasting pair—the one commanding in voice and figure, full of invention and a cheerful pretence of intolerance, and the other the equally resourceful, younger man who seemed able to rouse his companion to enthusiasm or indignation at will

" Throughout life Broom's spare figure and clear, alert mind seemed to reflect the bracing influence of a Fife upbringing He was well read and enjoyed discussion on many general subjects, with a genially critical ear for doubtful conclusions I well remember an occasion when he carried on a long and lively discussion on the politics of William the Silent with a Dutch professor, and the rest of us were very grateful to him for being able to provide, unprepared, such a suitable subject for our guest

" We have lost prematurely a scholarly scientist and a modest, stimulating companion "

In 1933 Dr Broom married Margaret Ethel Curtis, who survives him

ROBERT KLEIN

M D Prague

Dr Klein, consultant psychiatrist at the Crichton Royal Hospital, Dumfries, died on March 4 at the age of 64

W M-G writes " When Klein came to this country in 1939 he was already well known on the Continent as one of the most gifted and promising pupils of Arnold Pick and E Gamper His most original contribution at that time was on the function of the parietal lobe, which he considered to be the cerebral centre of integration of the highest developed tool of man the human hand

" After some initial difficulties, Klein, who had lost his home, position, and property, adapted relatively well to the life and professional demands of this country He not only worked as a practising psychiatrist in several hospitals, but also soon returned to his scientific interests, and continued his studies of brain-damaged patients, cerebral tumours and injuries, hæmorrhages and softenings, and carried further his publications of case-material based on minute and refined examinations of the patient's behaviour and performance His English papers included articles on the biochemistry of short-cycle periodic psychoses, neurological and psychological observations after electroconvulsions, and the immediate effects of prefrontal leucotomy His manual *Clinical Examination of Patients with Organic Cerebral Disease* (1957) describes his methods of investigation and examination of patients with focal organic lesions and also reports precise differentiations of symptoms based on his own observations

" Perhaps the most characteristic feature of his working method was his persistent dissatisfaction with what his analysis of symptoms had achieved so far He stimulated clinical and research work in all hospitals in which he was working, and he was most helpful to younger colleagues His scholarly personality, quiet and modest, and his unassuming and attentive understanding of his patients earned him respect and admiration "

CHARLES KNIGHT McDONALD

M D Edin , D P H

Dr McDonald, bacteriologist to Lewisham Hospital, died on Feb 6 at the age of 47

Dr McDonald was the elder son of the late Alexander McDonald of Perth, and qualified from the University of Edinburgh in 1936 After holding appointments as assistant bacteriologist and clinical tutor at Edinburgh Royal Infirmary he was appointed county bacteriologist for Ayrshire From 1945 to 1947 he served with the Friends' Ambulance Unit in China, where he met many hardships On his return he became pathologist at the Mental Hospitals Group Laboratory at West Park Hospital, and in 1948 he was appointed pathologist at Lewisham group laboratory, where he was in charge of the bacteriological department

E N A writes " During his period at Lewisham Dr McDonald showed a very wide interest in the development of the hospital as a whole, and apart from his bacteriological work, in which he maintained a meticulously high standard, he was actively concerned in the rebuilding of the hospital, particularly in the organisation of central sterilisation facilities

" Outside the hospital he had many interests he was on the local committee of the Labour Party, a governor of the Lewisham Prendergast School, manager of several primary schools, chairman of the Euthanasia Society, and a member of council of the Ethical Union He was interested in music—classical and jazz—modern art, and the theatre, Shakespeare in particular, and he often visited Stratford

" He was an individualist, and did not conform to any pattern, his cars were often a surprise to his colleagues—from a sedate Wolseley he graduated to a TR2, followed this by a Heinkel ' bubble car ', then a Land Rover (to move gravel and cement at his house at Chislehurst), and finally an Austin A40 we all wondered what would be the next

" He was a man of very strong character and decided views which he was not afraid to put forward and fight hard for, whatever the majority on the other side His absolute honesty of purpose made his opponents appreciate his views, even if they disagreed with them. His main personal attribute was one of kindness and sympathy his relations with all his colleagues were most cordial, and the junior staff found him an approachable and sympathetic friend."

Dr TOM D SPIES

P H M -B writes

" Your obituary of Tom D Spies did not sufficiently emphasise the very great contribution he made to the therapeutics of tropical disease.

" His introduction of nicotinic acid for the treatment of pellagra had many, and quite unsuspected, repercussions It was not in vitamin-B_2 deficiencies alone that nicotinic acid was found to have a place, its use extended to dermatology, otorhinology, and mental disease The credit for the discovery of folic acid as a specific for tropical sprue and nutritional anæmia must also go to Spies, who first applied it to the treatment of this disease in 1946 Its almost miraculous action was soon recognised and it provided a long-sought remedy Since its introduction the treatment of tropical sprue has been revolutionised, so much so that this ancient scourge of India and Ceylon has almost disappeared, in contrast to my experiences in my early days, fifty years ago

" These are some of the reasons why the name of Spies should go down in medical history as one of the benefactors of mankind. It is not only for these very considerable advances in our therapeutic armamentarium that we should honour him, but also for his unfailing courtesy and helpfulness to those on this side of the Atlantic who sought his aid and advice "

News

University of London

Mr G W Taylor, reader in surgery at St Bartholomew's Hospital Medical College, has been appointed to the chair of surgery at that college

Mr G W Taylor, who is 39 years of age, qualified from St Bartholomew's Hospital, London, in 1943 After service with the R.A M C. he held a house-surgeon appointment at Edgware General Hospital and took the F R.C.S in 1948 In 1949 he was appointed research assistant to the surgical professorial unit at St. Bartholomew's Hospital, and in 1950 as a Fulbright scholar was awarded a surgical fellowship at Stanford University, San Francisco In 1951 he was appointed chief assistant in the surgical professorial unit at Barts In 1952 he was awarded the B M A. Walter Dixon research scholarship, and in 1955 he took the M.S degree He was appointed to his readership in 1955 His published work includes papers on peripheral vascular disease, lymphœdema, and wound infection

The title of professor of hæmatology in the university has been conferred on Dr W M Davidson in respect of his post at King's College Hospital Medical School

Dr Davidson, who is 50 years of age, qualified from the University of Aberdeen in 1934 After holding appointments in Aberdeen Royal Infirmary he became lecturer in pathology in the university He served with the R.A M C throughout the war In 1948 he was appointed clinical pathologist to King's College Hospital and Medical School In 1957 he took the degree of M.D Aberd. with honours His published papers include investigations on congenital anomalies, on iron storage and anæmia, and on a morphological sex difference in the polymorphonuclear neutrophil leucocytes He has also contributed chapters to *Rose & Carless' Surgery*

The title of professor of bacteriology in the university has been conferred on Dr A C Cunliffe in respect of his post at King's College Hospital Medical School

Dr Cunliffe, who is 47 years of age, was educated at Rugby School, the University of Cambridge, and St. George's Hospital After qualifying in 1937 he worked at the London County Council's central histological laboratory In 1940 he was appointed assistant pathologist in the Emergency Medical Services From 1941 to 1943 he was demonstrator and from 1943 to 1946 assistant lecturer in bacteriology at University College Hospital Medical School. In 1946 he went into the Army as a specialist in pathology and was appointed a lecturer in pathology at the Royal Army Medical College, Millbank. After he was demobilised in 1948 he became bacteriologist at King's College Hospital and senior lecturer in the Medical School He was appointed reader in 1949 He is secretary of the Medical Research Council's committees on control of cross-infection and on sterilisation of syringes His published work includes papers on hospital infection of war wounds, epidemiology of carrier states and infections by staphylococci and proteus, and the *immune response* to diphtheria and tetanus toxoid.

The title of reader in oral anatomy in the university has been conferred on Dr H J J Blackwood in respect of his post at the Royal Dental Hospital of London School of Dental Surgery

University of Leeds

Dr D R. Wood has been appointed to the chair of pharmacology from Sept 1

Dr Wood was educated at Brasenose College, Oxford, and after graduating B A in 1942 he held a demonstratorship in the department of pharmacology at Oxford while continuing his medical studies He graduated B.M in 1945, and in the following year became lecturer of pharmacology and therapeutics at the University of Sheffield In 1952 he was appointed senior lecturer The year 1955–56 he spent as senior research fellow in the department of pharmacology at Yale Medical School In 1957 he gave up his lectureship in Sheffield to take up his present appointment as associate professor of pharmacology at McGill University, Montreal

The degree of CH.M has been awarded to F G Smiddy

University of Aberdeen

Dr Campbell Murray has been appointed second medical officer to the student health service

University of Edinburgh

On July 7 the honorary degree of LL.D will be conferred on Sir David Henderson

University of St. Andrews

Dr Gordon Sprunt has been appointed lecturer in therapeutics in the department of pharmacology and therapeutics, Queen's College

Royal College of Surgeons of England

On Thursday, April 14, at 5 P M , at the college, Lincoln's Inn Fields, London, W C 2, Mr Leon Gillis will give a Joseph Henry lecture He will speak on arm prostheses and appliances and their functional value in industry

British Tuberculosis Association

The provincial meeting of this Association will be held on Friday and Saturday, April 8 and 9, at the University of Southampton Further particulars may be had from the Association, 59, Portland Place, W 1

The Middlesex Hospital

The board of governors of this hospital have received from Major and the Hon Mrs Macdonald-Buchanan a gift of £140,000 to build a new training school for student nurses The board own the site for the new building, which will adjoin the main nurses' home It is hoped that the school will be ready for use within two years

World Health Day Exhibition

To celebrate World Health Day this year, the United Kingdom Committee for the World Health Organisation has arranged an exhibition of material to publicise the work of the W H O The exhibition will be open at the Charing Cross exhibition site from April 4 to 23 daily (except Sunday and Good Friday) from 11 A.M to 7 P M

First International Congress of Nephrology

This congress, organised by the Renal Association, la Societé de Nephrologie, the Scandinavian Society for Kidney Research, the American Society for Clinical Investigation, and the Societa Italiana di Nefrologica, will be held at Geneva and Evian (France) from Sept 1 to 4 Particulars may be had from Dr A A G Lewis, secretary of the Renal Association, c/o the Ciba Foundation, 41, Portland Place, London, W 1

New Hearing and Speech Centre

The Nuffield Foundation have offered a grant of £60,000 to build a centre, attached to the Royal National Throat, Nose and Ear Hospital and the associated Institute of Laryngology and Otology, for the diagnosis, assessment, and development of hearing and speech in children with impairment or total loss of these faculties, for research into congenital and acquired deafness, and for training of doctors and other professional workers

Medical Society of London

As principal guest at the dinner on March 17, Sir Arthur Bryant ranged gaily over the centuries

Advice to a young man starting medicine in the 1300s was that he should be careful not to pronounce upon a case " until he has seen it and knows what it is " The patient with measles was recommended to go to bed with a live sheep, for these animals are easily infected and draw the venom to themselves As a farmer, Sir Arthur felt that if the colleges could be induced to prescribe this remedy, it would be an enormous help to our struggling agriculture Our ancestors he said, had a sense that everything in the Universe was linked to everything else the flowers, the tides, and the seasons were all part of one design Contemplating the lot of man today, strap-hanging in the Tube and subjected to the noise and other trauma of work and home, he wondered whether environment had not something to do with failures in health The medical profession should sometimes corporately tell our rulers that their purpose should be to enable man to live according to his own nature

Dr R. Cove-Smith, the president, spoke of the society's excellent sessions and continuing liveliness Mr Guy Blackburn wittily proposed The Visitors, and Dr G F Abercrombie, president of the College of General Practitioners, remarked that, if there is any difficulty about disposing of the £500,000 that the Royal Commission proposes for distinction awards to practitioners, a possible destination might be the college's appeal

Empire Rheumatism Council

The Council has received a grant of £23,000 from the Geigy Pharmaceutical Co , Ltd , which will be used over the next seven years for travelling fellowships to be awarded in alternate years to research-workers in Britain and in other parts of the Commonwealth.

International Congress of Pædiatrics

This congress will be held in Lisbon from Sept 9 to 15, 1962 Further particulars may be had from the congress secretariat, Clinica Pediatrica Universitária, Hospital de Santa Maria, Avenida 28 de Maio, Lisbon, 4, Portugal

Pure Food Centenary

A conference to celebrate the centenary of the Adulteration of Articles of Food and Drink Act of 1860 is to be held in London from Sept 20 to 23 It is being sponsored by the appropriate Government departments and scientific societies The programme includes a paper by Prof A C. Frazer on the integration of food research Further particulars may be had from the secretariat of the centenary, 14, Belgrave Square, London, S W 1

During Sir Harry Platt's recent visit to Peru, Chile, and Colombia on behalf of the British Council, he was elected an honorary member of the Peruvian Academy of Surgery, the Society of Surgeons of Chile, the Chilean Society of Orthopædics and Traumatology, and the Sociedad Latino-Americana de Ortopedia y Traumatologia

Mr J D Martin, first assistant in the obstetric unit, University College Hospital, London, has been appointed senior assistant to the professor of obstetrics and gynæcology, University of Western Australia

Mr S Alan S Malkin has been appointed a member of the Industrial Injuries Advisory Council

The spring dinner of the Wessex Rahere Club will be held on Saturday, April 30, at the White Hart Hotel, Salisbury The secretary of the club is Mr A Daunt Bateman, 11, The Circus, Bath

British Standard (B S 3215 1960) specifies requirements for glass urine bottles of 850 ml (30 fl oz) capacity for male patients An appendix gives notes on the handling of glass urine bottles during cleaning and disinfection Copies (3*s*) may be had from the Sales Branch, British Standards Institution, 2, Park Street, London, W 1

CORRIGENDUM *Bronchography a Neglected Investigation?*—Dr Davies asks us to say that in this paper the amount of sucrose used in preparation of the Amethocaine Lozenges should have been given as 5 ounces and 212 5 grains

AXILLARY LYMPH-NODES IN PATIENTS WITHOUT BREAST CARCINOMA

T J McNair
M B Edin , F R C S E , F.R.C S
LECTURER IN SURGERY, UNIVERSITY OF EDINBURGH
H A F Dudley*
Ch M Edin , F R C S E
FORMERLY LECTURER IN SURGERY, UNIVERSITY OF EDINBURGH
From the Department of Clinical Surgery, University of Edinburgh

Examination of the axillary lymph-nodes is an important part of the investigation of patients with carcinoma of the breast, and the presence or absence of axillary lymph-nodes, and their mobility or fixation, are very often the features which determine the staging of the individual case Thus in the Manchester system of staging (1946), patients without palpable nodes are staged I, patients with palpable, but mobile, nodes are staged II, and patients with palpable and fixed nodes are staged IV In the more recent classification proposed by the research commission of the International Union against Cancer (1958) the same three groups would be stages I, II, and III respectively These widely different stages are associated with differing 5-year survival-rates, in some centres the stage into which the patient is placed will largely determine the type and extent of the surgical or radiotherapeutic measures to be employed

TABLE I—AGE-DISTRIBUTION OF SERIES

Age	Under 20	20–29	30–39	40–49	50–59	60–69	70 plus
No of patients	4	5	6	8	10	10	19

TABLE II—FINDING OF NODES

—	Observer A	Observer B
Total patients with palpable nodes	34	31
Nodes in both axillæ	11	9
Nodes in left axilla	5	5
Nodes in right axilla	18	17
No nodes	28	31

TABLE III—AVERAGE NODE-FINDING AND OBSERVER DIFFERENCE

—	Observer A	Observer B
Total patients with palpable axillary nodes	34 (55%)	31 (50%)
	(average 53%)	
Observer difference	34 axillæ in 124 (27%)	

Considering the importance attached to clinical staging, little attention has been paid to the clinical pattern of axillary lymph-nodes in “ normal ” women, and our ignorance about this pattern is surprising Furthermore, the accuracy and the constancy of any single clinician’s examination have been too readily accepted in the past Disagreement between clinicians (whether surgeons or radiotherapists) is frequent Such arguments and doubts as these prompted the following investigations in an attempt to determine

1 In what percentage of normal females axillary nodes were palpable
2 The difference between the findings of any two clinicians in a significant number of patients
3 How wide was the range between the findings of different examiners

Investigation

The investigation was carried out in two parts

PART 1

Two observers (A and B) each examined the axillæ of 62 patients who were in hospital for treatment of conditions not related to their breasts or axillæ, and who did not suffer from any clinical lesion of the breast The findings of each examination were recorded on a standard form and transferred to punch cards Thus 248 axillary examinations were recorded in a group of apparently normal subjects

TABLE IV—OBSERVER DIFFERENCE AND BUILD OF PATIENT

Build	Difference	No difference
Slim	16	5
Normal	12	14
Obese	6	9

The age-distribution of these patients (table I) reflects the high average age of patients in a modern general surgical unit

The number of patients in whom observers A and B found palpable axillary nodes is shown in tables II and III The finding of nodes is seen to be fairly uniform for the two observers and does not seem to depend on technique Nodes were, however, apparently more common in the right axilla than in the left, and this may reflect a greater incidence of minor trauma and sepsis on the right side Observers A and B disagreed on the presence or absence of nodes in 27% of axillæ, but the incidence of disagreement was lowest in obese patients (table IV) This could have been explained by a failure to find any nodes whatever in the obese, but in fact the incidence of positive axillæ in obese patients was for both observers as high as in slim or normally built patients

The cases in which “ negative ” findings were recorded were separately analysed (table V) The observers agreed that the axillæ of 19 patients were completely negative However, observer A recorded as doubly negative (both right and left axillæ negative) only 8 patients whom observer B labelled positive, while observer B labelled doubly negative 15 patients whom observer A regarded as positive Observer B would therefore be much less likely to put a patient down from stage I to stage II than would observer A It could be concluded that observer A was capable of better discrimination, or that he was less likely to identify other structures as lymph-nodes than was observer B Alternatively it could be argued than when in doubt, observer A favoured the positive and observer B favoured the negative

TABLE V—“ NEGATIVE ” CASES

Agreed negatives	19
Disagreed negatives	
Observer A/Observer B	8
Observer B/Observer A	15

Not all the nodes found at this examination would be regarded as undoubtedly carcinomatous, but about one-third were described as firm or hard and one-half were estimated to be 0 5 in or more in diameter

PART 2

After analysis of the above results, we decided on a further clinical experiment Five clinicians (surgeons and

* Present address Department of Surgery, University of Aberdeen

TABLE VI—PATIENTS WITH BREAST PATHOLOGY

Serial no of patient	Breast lesion
1	Bilateral breast abscess
2	Tumour in left breast immediately behind nipple
3	Large tumour in upper outer quadrant of left breast continuing into tail of breast
4	Left breast previously removed by simple mastectomy with later radiotherapy, known at time of experiment to have skeletal metastases

radiotherapists) agreed to take part. 10 patients were selected and placed in random order. Each patient was masked and the body draped in such a way as to expose only the shoulders and axillæ; the breasts were concealed as far as possible. In 6 of these patients the breasts were normal on clinical examination and there was no reason for expecting the axillary glands to be enlarged. The other 4 had abnormalities of the breast or breasts as listed in table VI.

After the 10 patients had been placed in random order the five clinicians were invited to examine them independently.

The patients were examined by whatever method each examiner favoured: one examiner preferred the patients to lie down, the others all performed their examinations with the patients seated, although their technique varied greatly. The findings of each examiner were recorded on a standard form and transferred to punch cards.

Thus, 100 axillary examinations (10 patients, 20 axillæ, five examiners) were available for study. Of the 20 individual axillæ, 5 were "abnormal" (4 left and 1 right) and 15 were "normal".

Examination of patients without breast pathology.—Positive findings were recorded by the examiners in 48% of these examinations. Considerable differences were noted between the five examiners and the range was such that while one examiner recorded only 20% of all these axillæ positive, another recorded no less than 73% positive.

TABLE VII—FIVE CLINICIANS' SUMMARY OF RESULTS

—	Patients without breast pathology	Patients with breast pathology
Positive findings by 5 examiners	48%	48%
Disagreement between examiners	40%	35%

Examination of patients with breast pathology.—There were 4 "abnormal" left axillæ and 1 "abnormal" right axilla. Positive findings were again recorded in 48% of these examinations. Once more, considerable differences were noted between examiners and the range of positive finding varied from 20 to 80%.

Disagreement between examiners.—For each individual axilla, 5 examinations were recorded. There were thus 10 possible comparisons for each axilla. Forty per cent of "normal" axillæ were disputed and 35% of the "abnormal" axillæ were disputed (table VII).

It is of interest to note that patient 2 in table VI was variously placed in stages I to stage IV (Manchester staging) by different examiners.

OVERALL TOTAL OF POSITIVE AXILLÆ

Combining the results obtained from both parts of the investigation in respect of the "normal" axillæ only, it was found that out of 308 examinations, 114 were positive for nodes—an overall rate of 37% in "normals".

Discussion

Part 2 of the investigation tends to support—and indeed magnifies—the findings of the two examiners in part 1.

The outstanding facts which emerge from this trial are:

(a) 37% of "normal" female axillæ had palpable axillary lymph-nodes. Thus, it is probable that about one-third of patients who develop a carcinoma in the breast may be placed in stage II for reasons in no way associated with their tumour or its dissemination.

(b) In some 35–40% of cases clinicians differ on the presence or absence of nodes.

The high observer difference must raise grave doubts about the value of the present use of lymph-nodes as a means of staging. If such difference occurs over the very presence of nodes, how much more likely is it that disagreement will exist over such characteristics as their degree of fixation or their consistence not only in the axilla but also elsewhere?

Since it was our finding that 37% of axillæ had a palpable enlarged node even before carcinoma of the breast develops, it may be deduced that about one-third of carcinomatous patients will be wrongly placed in stage II when they rightly belong in stage I. The bearing of these findings on the published results of treatment of breast cancer are of great interest. As an example, we abstracted the figures of one series (McWhirter 1955). If it be allowed that of every 100 patients with "early" carcinoma of the breast approximately 54 are usually placed in stage I and 46 in stage II, and that in the same series the five-year cure rate in stage I is 71% and in stage II is 56%, then it can be calculated that stage II properly contains only 14 patients and that only 3 survive to five years when corrections are applied for the initial 37% error in staging. For the same series, this alters the stage II cure-rate at five years from 56% to 21%. This corrected cure-rate (21%) at five years when axillary lymph-nodes are involved, surely leaves much to be desired and much to be achieved in the treatment of early carcinoma. These figures make it seem unlikely that clinical classification of breast cancer by examination of the axillary lymph-nodes has any part to play in the management of the disease.

It is not the purpose of this paper to criticise any individual method of treatment, but rather to call attention to anomalies in the criteria upon which the results of treatment may be assessed. The numerical stages into which a disease is subdivided should represent the progress of the disease process. Therefore, the criteria upon which stages are decided must themselves be concerned with the disease and not with chance circumstances. When chance occurrence enters the staging procedure, the stages become not only valueless but also misleading. In a broader view, the results also demonstrate two truths insufficiently realised in surgical practice: first, that self-evident clinical premises require periodic re-examination, and secondly, that gross differences in clinical observation between examiners are commonplace.

Summary

A study of the incidence of palpable axillary lymph-nodes in normal females is described. Palpable nodes were found in 37% of female axillæ, without evident causative disease.

In 35–40% of patients differences of opinion were found between examiners.

The bearing of these findings on the clinical staging of carcinoma of the breast is discussed: the use of axillary lymph-nodes for this purpose is seen to be valueless and misleading.

PROFESSOR OF CHILD HEALTH, UNIVERSITY OF BRISTOL

HYPERBILIRUBINÆMIA and kernicterus are sometimes seen in premature infants who show no evidence of iso-immunisation, but the recorded incidence varies considerably throughout the world During 1948–54 kernicterus without evidence of hæmolytic disease was found post mortem in 67 from a total of 2599 premature infants nursed in the two units in Bristol—an incidence of 2 6% Crosse et al (1955) reported the incidence of kernicterus as 2 3% of all admissions to their premature-infant units in Birmingham, the highest figure being 4 1% in one unit Through the courtesy of Dr Clement Smith and Dr Stewart Clifford, a survey was made of all postmortem reports on infants in the Boston Lying-in Hospital during 1948–54 483 necropsies were performed, 26 of them in infants who died after three days, but only 3 cases of kernicterus without isoimmunisation could be found in the whole series This contrasts with the experience in Britain during the same period

A study of serum-bilirubin levels in premature infants without evidence of isoimmunisation was started in July, 1954, among babies admitted to the two Bristol premature-baby units At the end of 1954 we noticed that kernicterus had in fact neither been suspected clinically nor demonstrated post mortem in any of the premature infants who had died during the previous twelve months, this contrasted strikingly with the experience of the previous seven years

Shortly afterwards reports began to appear of the possible association of large doses of the synthetic vitamin-K analogue, tetrasodium 2-methylnaphthalene-1 4-diol phosphate, known as ‘ Synkavit ’ or ‘ Kappadione ’ (Allison 1955, Crosse et al 1955, Laurance 1955) Later close correlation between the intramuscular dosage of this drug and the level of serum-bilirubin was demonstrated by several workers (Bound and Telfer 1956, Meyer and Angus 1956, Stroder et al 1957)

Inquiry into the use of synthetic vitamin-K analogues in our two units revealed that until December, 1953, synkavit had been given routinely to all babies admitted, as three intramuscular injections of 10 mg during the first twenty-four hours, followed by oral treatment with 10 mg t.d s for the next three days If the infant's condition was too poor to allow of oral feeding, two or even three further intramuscular injections were given during the second twenty-four hours Thus all infants were given 30 mg and some had as much as 60 mg by intramuscular injection in the first forty-eight hours of life.

Unknown to us, in January, 1954, synkavit had been replaced by a different vitamin-K analogue known as ‘ Vikastab ’ (menaphthone dipotassium sulphate), given in the same dosage as synkavit Because the experimental work of Allison et al (1956) suggested that other synthetic vitamin-K analogues might be less toxic than synkavit, we decided to study the effect of vikastab in different doses on the serum-bilirubin level

The Investigation

The babies studied were all nursed in the premature units of two Bristol maternity hospitals between July, 1954, and December, 1956

All weighed 5 lb 8 oz or less, and the routine care (including indications for giving oxygen and antibiotics) were the same in the two units Maternal analgesia and obstetric techniques were also comparable.

All babies were included except those who showed evidence of Rh, ABO, or other blood-group incompatibility, those in whom technical difficulties prevented the collection of blood samples, and those who died during the first forty-eight hours

The slightly modified method of Evelyn and Malloy was used for serum-bilirubin estimations, which were all made on venous blood usually taken from the median basilic vein, and which were performed in the laboratory of Southmead General Hospital. Whenever possible the first estimation was made on umbilical-cord blood.

Because the work of Hsia et al (1953) suggested that the highest level of bilirubin was likely to be reached on the fourth day, during the first year samples were taken on the second and fourth days Billing et al. (1954), however, showed that the time of the peak level of bilirubin depended on maturity, therefore from Aug 1, 1955, the maximum serum-bilirubin level was determined by daily estimations which were continued until the level dropped significantly

Thus, during the first year of the investigation serum-bilirubin levels were estimated until the fourth day on babies who were given 30–60 mg of vikastab by intramuscular injection in the first forty-eight hours Later, on admission to the premature nursery, the infants were allotted consecutively to one of three treatment regimes

1 No synthetic vitamin-K analogue was given.

2 Vikastab 5 mg was given as a single intramuscular dose within an hour of birth.

3 Vikastab 5 mg was given intramuscularly 2–3 times at twelve-hourly intervals

Results

436 cases were available for final assessment of results These were divided into four groups according to vitamin-K dosage

1	No vitamin K		107 infants
2	Vikastab	5 mg	94 ,,
3	,,	10–15 mg	138 ,,
4	,,	30–60 mg	97 ,,

For purposes of analysis the infants were also divided into groups according to gestational age, which was estimated in the usual way by calculation from the mother's last menstrual period. In a few cases the clinical assessment of the infant, and particularly the development of sucking and swallowing reflexes, was also taken into consideration in allotting the case to a maturity group Relation of serum-bilirubin level to estimated maturity rather than to birth-weight was thought to be more accurate because some twins were included in this survey, and their birth-weights are usually lower than singletons of the same maturity When the analyses were made, however, there were no significant differences between comparison of serum-bilirubin levels with either estimated maturity or birth-weight.

Table I shows the mean values for maximum serum-bilirubin levels in each maturity group for each treat-

Vitamin K=Dipotassium menaphthone bisulphate

ment regime in 315 cases The most obvious finding is the relation between maximum serum-bilirubin level and maturity, which confirms the work of Billing et al (1954) No significant difference was found in the serum-bilirubin levels in each maturity group between those babies who had no vikastab and those who had either of the selected dosage scales Fig 1 shows that the slope of the regression lines is the same in all cases

The figures for the 377 infants in whom fourth-day serum-bilirubin levels were estimated were also analysed similarly (table II), again no statistical difference emerges between the fourth-day serum-bilirubin levels in each maturity group for any of the four different regimes, and, as before, the slope of the regression lines is similar (fig 2)

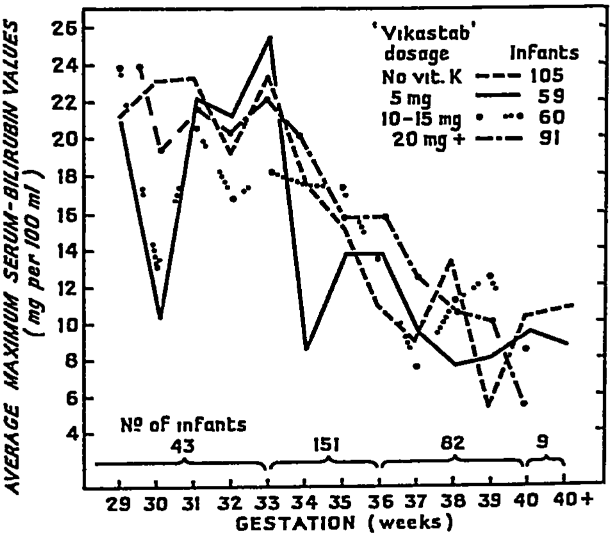

Fig 1—Maximum serum-bilirubin levels related to maturity and dosage of vitamin K.

Discussion

That the brain damage of kernicterus results from high levels of unconjugated bilirubin in the blood-plasma is now well established (Day 1954, Lathe 1954, Waters and Britton 1955, Zetterstrom and Ernster 1956) Fat-soluble bilirubin is excreted by conjugation with glucuronic acid in the liver to form water-soluble glucuronides (Lathe and Walker 1957) There is evidence that in the newborn

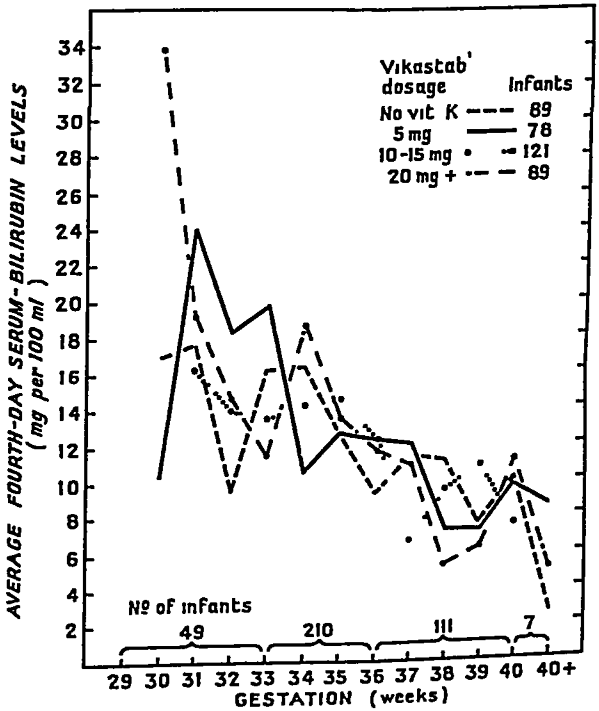

Fig 2—Fourth-day serum-bilirubin levels related to maturity and dosage of vitamin K

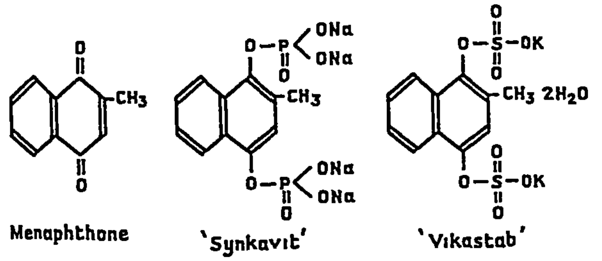

Fig 3—Synthetic vitamin-K analogues

Menaphthone (2-methyl-1 4 naphthoquinone) has much vitamin-K activity and is reasonably stable, 'Synkavit' (diphosphoric acid ester of 2-methyl-1 4 naphthohydroquinone) and 'Vikastab' (dipotassium 2-methyl 1 4-naphthalene bisulphate dihydrate) are both water soluble

infant capacity to conjugate bilirubin is limited, probably because of deficiency in development of the transferase enzyme system, therefore very slight increase in the production of bilirubin is liable to cause high serum levels and severe jaundice In the most immature infants the enzyme system is likely to be less well developed, hence the frequent appearance of so-called physiological jaundice in immature infants

Experiments have also shown that conjugation of bilirubin is inhibited by various chemicals, including potassium cyanide, salicylates, and carbon monoxide, and by placental steroids and hypoxia Clinically, synkavit and 'Sulfasoxazole' have also been associated with hyperbilirubinæmia, and the inference is that these drugs interfere with bilirubin conjugation

Naturally occurring vitamin K was originally used for treating and preventing hæmorrhage in the newborn, but, as this substance is fat-soluble, intramuscular injections in infants tended to cause abscess formation Hence synthetic water-soluble analogues have largely replaced this drug in therapy of the newborn It is of interest that synkavit first came into routine use in Bristol and many other British obstetric departments during 1947

The basis of all water-soluble analogues of vitamin K is menaphthone, and various radicles are added—synkavit differs from vikastab in that the disodium-phosphate radicles are replaced by dipotassium sulphate (fig 3) In this trial we have shown that hyperbilirubinæmia was related only to immaturity, confirming the findings of Billing et al (1954), and that vikastab had no effect on its development when given intramuscularly in small or larger doses during the first two days of life We may assume, therefore, that vikastab does not inhibit conjugation of bilirubin

Conclusions

From this study the following conclusions may be drawn

1 Hyperbilirubinæmia in premature babies is primarily related to immaturity

2 The synthetic vitamin-K preparation, menaphthone dipotassium bisulphate ('Vikastab'), did not seem to influence the development of hyperbilirubinæmia in immature babies when given intramuscularly in divided doses up to a maximum total dose of 60 mg during the first two days of life, nor was the risk of kernicterus increased

If a vitamin-K water-soluble analogue is considered necessary for a newborn infant, it is desirable that the preparation chosen should not interfere with the normal processes of bilirubin excretion Vikastab seems to be safe and it can if necessary be given in considerably higher dosage than synkavit

Summary

Serial serum-bilirubin levels have been studied in 436 newborn premature infants to determine the maximum level of bilirubin

The maximum and fourth-day serum-bilirubin levels of premature infants given a synthetic vitamin-K preparation—menaphthone dipotassium bisulphate ('Vikastab')—in various dosages intramuscularly during the first two days of life have been compared with the serum-bilirubin levels of an unselected group of premature infants who had no vitamin-K analogue

The development of hyperbilirubinæmia was related to immaturity, and was unaffected by this vitamin-K analogue even in relatively high doses

We are extremely grateful to Dr F J W Lewis and his senior biochemical technician, Mr Cyril Chapman, A M I C T, who estimated the bilirubin levels, and to Miss E H L Duncan, statistician, department of public health, University of Bristol, for the statistical analysis of the data and preparation of figs 1 and 2 A research grant from the South Western Regional Hospital Board has enabled Dr Berry to assist in this investigation

BLOOD-VOLUME IN ELDERLY ANÆMIC PATIENTS FOLLOWING BLOOD-TRANSFUSIONS

Stig Bryde Andersen
M D Copenhagen

From Surgical Department A and the Department of Clinical Biochemistry and Physiology, Bispebjerg Hospital, Copenhagen

In elderly anæmic patients the majority of surgeons attempt to obtain a normal hæmoglobin level preoperatively by means of blood-transfusions, but such transfusions may overload an already weak cardiovascular system

In 1909 Boycott and Douglas determined the blood-volume in three rabbits daily for a period These animals received two to three transfusions at intervals of some days The transfusions comprised 25–40% of the blood-volume prior to transfusion Boycott and Douglas found that the blood-volume did not alter but that the cell-volume increased more or less according to the quantity of cells administered, while the plasma-volume fell correspondingly

Following subsequent investigations (Boycott and Douglas 1910, Boycott and Oakley 1933, 1934) Boycott revised his opinion and concluded that it was the plasma-volume that was regulated After transfusion the blood-volume rose according to the quantity of cells infused, while the plasma-volume remained unchanged.

In more recent years similar studies have been made in dogs (Deavers et al 1957, Huggins et al 1956, 1957, 1958, Smith et al 1956, 1959) Otherwise there have been very few such investigations (Guyton et al 1950, 1951, Spencer 1951)

These investigations have one finding in common—namely, that plasma disappears from the circulating blood after a blood-transfusion Occasionally, more plasma disappears than is infused With large transfusions, corresponding in volume to the blood-volume before trans-

TABLE I—DATA ON THE 24 PATIENTS BEFORE TRANSFUSION

Hb I=before transfusion Hb II=after transfusion
* These patients had malignant disease

fusion, it is difficult to account for the entire quantity of cells given in the transfusion The phrase " trapped cells " is employed in this connection (Huggins et al 1956, Smith et al 1956) Various investigations suggest that this quantity of cells is trapped particularly in the liver (Deavers et al 1957) With smaller transfusions the increase of cell-volume corresponds to the volume infused

In man the conditions have been investigated particularly in patients submitted to operations (e g , Norlander 1955, Prentice et al 1954, Wiklander 1956, Williams and Parsons 1958) In man in a steady metabolic state, only a few investigations have been undertaken—as a rule on a small scale (Korth 1941, Pellegrini 1934, Wetzel 1939, Wollheim and Schneider 1958)

The most thorough investigations were undertaken by Wollheim and Schneider These workers found that, after a transfusion of approximately 10% of the original blood-volume, the blood-volume increased in some patients but not in others In the former group the blood-volume was on average 70 ml per kg body-weight, while in the latter group it was 77 ml per kg These workers therefore consider that the changes in the blood-volume depend on the magnitude of the blood-volume before transfusion However, it does not appear clearly from their article whether this difference is statistically significant It is furthermore doubtful whether this classification of the material is statistically correct

Material

In table I the data concerning the patients are tabulated Columns 6 and 7 show the hæmoglobin levels before and after transfusion

A total of 24 patients (10 males and 14 females) was investigated These patients will be analysed together as the results do not differ for the sexes Their average age was 58 years 9 had cancer of the alimentary canal and the remainder had non-malignant diseases Cardiac disease was not demonstrated in any patient

During the period of investigation none of the patients was submitted to operation and none had hæmorrhage

Methods

Blood-volume was determined between one and twenty-four before the first transfusion, and again between two hours r days after the last transfusion

tients received at least two transfusions, some received or four transfusions, and 1 received ten transfusions in course of ten days No patient received more than two sfusions in one day Each transfusion consisted of 450 ml blood, of which 250 ml was plasma and 200 ml blood-cells 60 ml ACD solution was added to each bottle of blood as an anticoagulant These values were not worked out for each individual bottle of blood, but the results of spot tests agreed with these values

The plasma-volume was determined with T-1824, by Jarnum's (1959) modification of Allen's (1953) extraction method

The blood-volume was determined from the plasma volume by means of the hæmatocrit value The body hæmatocrit was calculated from the venous hæmatocrit by correcting with the factor 0 91 (Chaplin et al 1953)

The venous hæmatocrit was determined on heparinised blood in a modified Wintrobe tube rotated for half an hour at 3000 r p m with a radius of 15 cm to the centre of the column of blood-cells The venous hæmatocrit was corrected for " plasma trapping " with the factor 0 94, which was determined for the centrifuge employed for the hæmatocrit determinations. The formula for the blood-volume (B V) was thus

$$\mathrm{B\,V} = \frac{\text{plasma-volume} \times 100}{100-(\text{hæmatocrit} \times 0\ 94 \times 0\ 91)}$$

In order to control reproducibility, the blood-volume was determined at intervals of a few days in 5 of the patients during a period in which they did not receive treatment. In 4 of the patients the blood-volume was determined twice and in the 5th thrice The variations in the blood-volume in relation to the first blood-volume recorded were −3 2%, −4 6%, +1 5%, −0 3%, +0 9%, +0 3%

In all the blood-volume determinations Kjeldahl analysis was undertaken on the serum to determine the total protein, and a conversion factor of 6 25 was employed The serum-proteins were fractionated by means of paper electrophoresis by the method of Laurell et al (1956) The total circulating albumin, circulating globulin, and circulating γ-globulin before and after transfusions were calculated The hæmoglobin was determined spectrophotometrically from dilution of oxyhæmoglobin

Results

The following is a typical example of the investigation and its results

The patient, a man aged 77, had a duodenal ulcer with melæna and hæmatemesis No gastrointestinal hæmorrhage had occurred in the week before the first day of the period of the investigation

1st day —Blood-volume (B V) I=2850 ml (62 0 ml per kg), plasma-volume (P V) I=2230 ml (48 5 ml per kg), cell volume (C V) I=620 ml (13 5 ml per kg), Hb I=8 9 g per 100 ml

2nd-5th days —Transfusion 1 bottle of blood on each of these four days total 1800 ml (i e , $\mathrm{Tr}_{\mathrm{BV}}$=1800 ml , $\mathrm{Tr}_{\mathrm{PV}}$=1000 ml ,

Symbols are explained in text
* This patient received in addition to the blood-transfusion one litre of human plasma during the period of investigation

Tr_{CV} = 800 ml, where Tr_{BV} is the amount of blood transfused, and Tr_{PV} the volume of plasma, and Tr_{CV} the volume of cells contained in the transfused blood)

6th day —B V II = 3050 ml, P V II = 1780 ml, C V II = 1270 ml, Hb II = 16 0 g per 100 ml

$$\frac{BV\ I + Tr_{BV}}{BV\ I} = 163\% \qquad \frac{BV\ II}{BV\ I} = 107\%$$

$$\frac{CV\ I + Tr_{CV}}{CV\ I} = 229\% \qquad \frac{CV\ II}{CV\ I} = 209\%$$

$$\frac{PV\ I + Tr_{PV}}{PV\ I} = 145\% \qquad \frac{PV\ II}{PV\ I} = 80\%$$

Thus after four transfusions totalling 1800 ml (63% of the original blood-volume) the hæmoglobin level had increased from 8 9 g per 100 ml to 16 0 g per 100 ml, but the rise in blood-volume was only 200 ml (7%) The cell-volume increased more or less according to the quantity administered, while the plasma-volume decreased

Table II shows the volumes before and after transfusions for all the patients, the amount of blood transfused, and the plasma- and cell-volume in the transfused blood The cases are arranged in order according to the amount of blood transfused this amount is expressed as volume of blood transfused in relation to blood-volume before transfusion $\left(\frac{Tr_{BV}}{BV\ I} \times 100\right)$ Thus it should be possible to compare results from two patients even if they have very different blood-volumes

Fig 1 represents graphically the changes in the blood-volume in each case All volumes are expressed as percentages of blood-volume before transfusion, so values higher than 100% indicate that blood-volume has increased after transfusions, while values below 100% indicate that blood-volume has decreased after transfusions

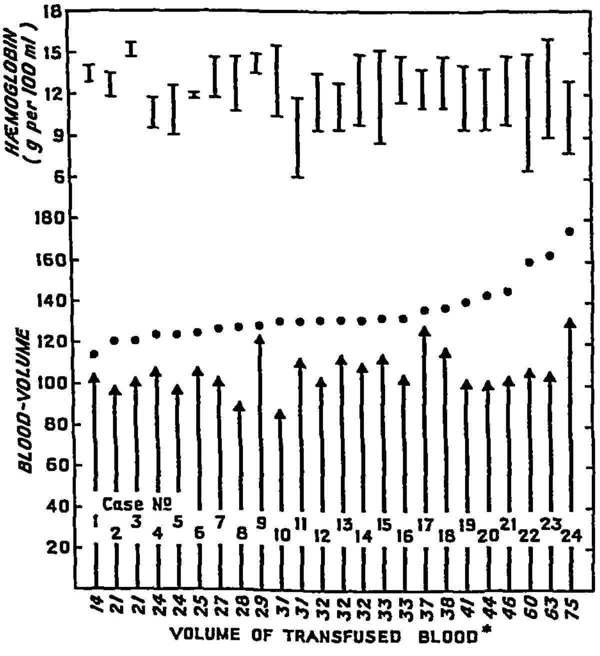

Fig 1—Changes in blood-volume after transfusion

Arrows indicate blood-volume actually found after transfusion $\left(\frac{BV\ II}{BV\ I} \times 100\right)$ The average was 109% (range 89–133%)

Closed circles indicate calculated blood-volume if this volume increased according to the volume transfused $\left(\frac{BV\ I + Tr_{BV}}{BV\ I} \times 100\right)$ The average was 136% (range 114–175%)

* *Transfused volume of blood* = $\frac{Tr_{BV}}{BV\ I} \times 100$

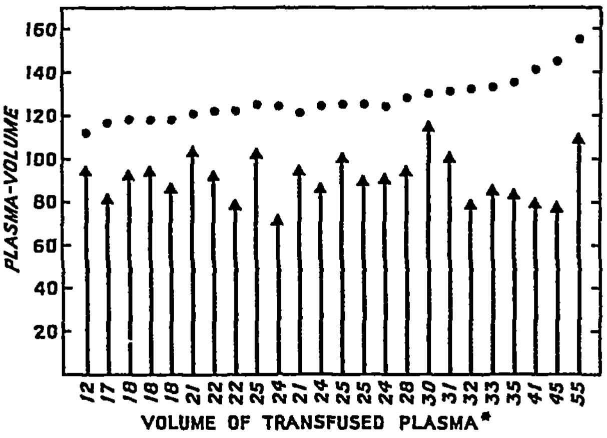

Fig 2—Changes in plasma-volume after transfusion

Conversions as in fig 1

Arrows = $\frac{PV\ II}{PV\ I} \times 100$ The average was 94% (range 74–117%)

Closed circles = $\frac{PV\ I + Tr_{PV}}{PV\ I} \times 100$ The average was 128% (range 112–155%)

* *Volume of transfused cells* = $\frac{Tr_{PV}}{PV\ I} \times 100$

Fig 1 shows that in no case did the blood-volume increase by the quantity transfused In 2 cases, however, lower blood-volumes were found after transfusion than before transfusion, and in 2 cases the blood-volume was unaltered There is only a very slight tendency for the blood-volume to increase when the magnitude of the transfusion is increased On average, the patients received transfusions amounting to 36% of the original blood-

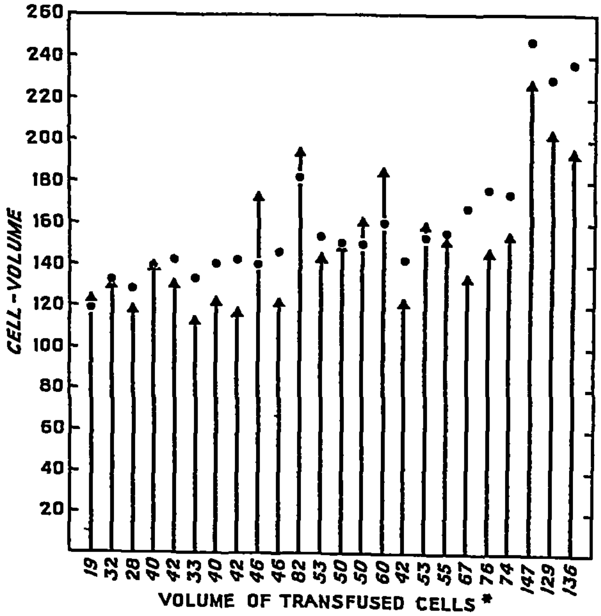

Fig 3—Changes in cell-volume after transfusion

Conversions as in figs 1 and 2

Arrows = $\frac{CV\ II}{CV\ I} \times 100$ The average was 152% (range 119–229%)

Closed circles = $\frac{CV\ I + Tr_{CV}}{CV\ I} \times 100$ The average was 160% (range 119–247%)

* *Volume of transfused cells* = $\frac{Tr_{CV}}{CV\ I} \times 100$

volume, and they reacted to this with an average increase of 9%, with rather extensive scatter round this figure

Fig 2 shows plasma-volumes expressed similarly to the total blood-volumes (fig 1) In most cases the plasma-volume fell after transfusions, denoting that more plasma disappeared from the circulating blood than was infused In only 6 cases did the plasma-volume increase, and in no case was the increase as large as the quantity of plasma infused There was no tendency to increase or decrease with increase in the magnitude of the transfusion The average amount of plasma administered to each patient corresponded to 28% of the original plasma-volume, and, on average, the plasma-volume fell by 6%

Fig 3 shows cell-volumes The increase in the cell-volume was found to lie at the lower limit of that which might be anticipated On average, 60% of the original cell-volume was administered in the transfusion, and on average only 52% rise was found, this difference is statistically significant In 5 cases the cell-volume increased by a greater volume than that administered by transfusions If this is not due to an error in the method, it may be attributable to the fact that body hæmatocrit has become lower or that capillary permeability has become greater after transfusions so that the plasma-volume and with it the cell-volume is estimated too high

The average serum-proteins after transfusions, expressed as percentages of the pre-transfusion levels, were as follows

Albumin 103% (range 65–134%)
Globulin 101% (range 70–127%)
γ-globulin 102% (range 73–139%)

Thus the circulating quantities of albumin, globulin, and γ-globulin remained, on average, the same after the transfusions despite the relatively large quantities of protein in the transfused blood This holds true for all the fractions investigated, despite the difference in the size of molecules The scatter was fairly wide

Discussion

The material investigated is far from uniform as regards both the patients and the experimental conditions Both the volume of the transfusions and the time which elapsed between the transfusion and the determination of the blood-volume varied greatly This restricts the conclusions which may be drawn

No relationship was found between the magnitude of the blood-volume per kg body-weight before transfusion and the changes resulting from transfusion Thus the postulates of Wollheim and Schneider (1958) were not confirmed

There can be no doubt that after transfusion considerable quantities of plasma and protein disappear from the circulating blood—probably into the extracellular spaces This cannot be proved directly as the methods available for determining the extracellular space in man have an experimental error of approximately one litre (Ikkos and Luft 1957)

The several investigators who have expressed the opinion, following experiments on animals, that the plasma-volume and not the total blood-volume is regulated following blood-transfusion found that the plasma-volume was unchanged while the blood-volume rose in accordance with the volume of cells administered (Krumbhaar and Chanutin 1922, Seavers and Price 1949) The reason for this finding may be that the blood-volume was determined so soon after the transfusions that the regulating mechanism had not yet operated completely The findings in 7 of the patients in the present investigation support this hypothesis In these patients the blood-volume was determined immediately after transfusion and two to four days after that In the interval between these two determinations the blood-volume decreased to about the original value This took place by reduction in the plasma-volume, while the cell-volume remained more or less unchanged

This reduction of plasma-volume explains the following observation during the first days after transfusion treatment has been terminated the hæmoglobin-level of the blood often increases by 10–20%

Certain investigations suggest that this regulation of blood-volume may be explained by simple physicochemical forces (a) increase of venous pressure (e g, Valsalva's manœuvre (Brown et al 1948) causes diffusion of fluid from the circulating blood (b) the venous pressure is slightly raised for a long time after a blood-transfusion, probably until the blood-volume is normal again (Gauer et al 1956), (c) after infusion of plasma-expanders the capillary permeability appears to be increased (Wasserman et al 1955) It appears reasonable to assume that blood-transfusions have the same effect Future investigations will reveal what this implies for the exactitude of the plasma-volume determinations by protein-tagging methods following blood-transfusions

The regulation of blood-volume after transfusions may therefore be explained as follows the increase in hydrostatic pressure in the veins associated with increased capillary permeability causes the loss of plasma and protein from the circulating blood

Conclusions

The object of the present investigation was to establish the extent to which blood-volume is increased in elderly people who receive blood-transfusions

It was found that in elderly anæmic people (average age 58 years) in a steady metabolic state blood-transfusions amounting to 14–75% (average 36%) of the original blood-volume produce (a) an increase in cell-volume approximately corresponding to the quantity of cells administered, (b) a reduction of plasma-volume, (c) a slight increase in total blood-volume (average 9% of the original blood-volume)

I suggest that the total blood-volume, and not only plasma-volume, is regulated by simple physicochemical forces which displace fluid and proteins from the circulating blood into the extracellular spaces

This investigation was supported by grants from Messrs Bang & Tegner Ltd , Copenhagen

THAT mongols have 47 chromosomes and are trisomic for one of the two short pairs of acrocentric chromosomes has been invariably demonstrated in the 30 cases reported so far (Lejeune et al 1959a and b, Jacobs et al 1959, Ford et al 1959, Book et al 1959) These two chromosome pairs are numbers 22 and 23 of Ford et al (1958), and, although they were not distinguished, it is now recognised that one is a little longer than the other and may exhibit a small "satellite" to the short arm Since there is now evidence that it is the longer satellited chromosome that is implicated in mongolism (Tjio and Puck 1958, Chu and Giles 1959), we shall refer to this chromosome as no 22 *

"Non-disjunction" at one of two meiotic divisions during gametogenesis, leading to the production of a gamete with 24 instead of 23 chromosomes, is the most probable origin of trisomy Because of the well-known maternal age effect in mongolism (Shuttleworth 1909, Jenkins 1933, Penrose 1933, 1934) it is generally assumed that the error is more likely to be one of oogenesis than of spermatogenesis Possibly other factors than those associated with advancing maternal age may cause mongolism, and it is conceivable that mongolism might arise through other chromosomal mechanisms, in which case chromosome studies might reveal the postulated differences

It is difficult to select mongols in whom such special ætiological factors and/or chromosomal mechanisms might have operated One approach might be dictated by the following considerations

It is likely that most mongols whose chromosomes have been studied and reported on were the offspring of older mothers The distribution of maternal ages at the birth of mongol children is known to be skew to the left and often frankly bimodal, as Penrose (1951, 1954a) has pointed out, with a peak at the average maternal age for normal controls and the major peak at a considerably higher age This skewness and bimodality can be interpreted as an expression of ætiological heterogeneity in respect of factors that relate mongolism to maternal age Furthermore, when mongolism is found in maternal (but not paternal) ascendants and collaterals, the *mean* maternal age at the birth of mongol children is significantly lowered (Penrose 1951) This also happens in the group of mothers who have more than one mongol child, though it is difficult to discern how much the lowering of the mean maternal age is independent of that which will automatically result from "having to fit" more than one affected child into a sibship (Penrose 1951) The lowering of maternal age in familial mongolism may indicate that genetic factors (in the mother) may increase the frequency with which "non-disjunction" occurs and render it less dependent upon advancing maternal age

It appeared that a study of the chromosomes of mongols born to young mothers might be rewarding It can be thought that this group may be compounded of at least three subgroups (1) where the condition is related to the same causes which produce mongols from older mothers, (2) where mongolism is familial (through the mother) or shows sibship concentration or both, and (3) a residual and probably miscellaneous subgroup where yet other factors than the above *may* operate

Material

We selected three mongol children because they were born from *young* mothers and there was no sibship or family concentration of mongolism Bone-marrow suspensions from these three mongols were sent to Harwell The observers there knew that the marrows were from mongols but did *not* know the special reason for the investigation or the criteria of selection of these patients Of these three marrow cultures, one failed and another yielded a chromosome count of 47, with trisomy of one of the two short acrocentric chromosomes presumably chromosome 22 The result in the third is the object of this communication

Case-record

A, a female born on Dec. 29, 1949, weighing 6 lb 14 oz, was diagnosed neonatally as a mongol Her mother, who was 21, had an uneventful pregnancy She was X-rayed repeatedly for inactive pulmonary tuberculosis (Dec 13, 1948, and March 21, July 4, Aug 29, and Oct 31, 1949) A's father was 23 years of age There is no family history of mongolism, mental defect, or any other abnormalities The mother had one other pregnancy resulting in the birth of a normal male in 1952 A is a typical mongol and shows no associated abnormalities (fig 1) She was admitted to the Fountain Hospital at the age of $3^{1}/_{4}$ years Her intelligence-quotient has varied between 38 and 40 on repeated testing on the Merrill-Palmer scale or the Stanford-Binet (T M revision) form L Each palmar A T D angle (Penrose 1954b) measures 91°

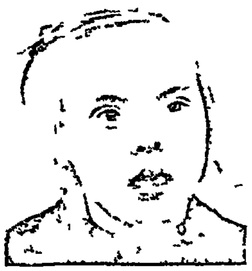

Fig 1—Mongol child, aged 10 years

Cytological Observations

The marrow was processed according to the technique of Ford et al (1958) Preparations were made and examined independently by two observers (C E F, C M C) Their findings, compared after completion of the observations, agreed The counts, summarised in the accompanying table, show that the chromosome num-

ber was 46. On detailed analysis of 15 cells, only 4 short acrocentric chromosomes were found, as in normal females (fig. 2). Of the group of 6 chromosomes of pairs 14, 15, and 16 normally present, 5 were found, but there were 17 medium-length chromosomes instead of 16 as in a normal female. Careful matching of these chromosomes in photographs of five cells revealed that the "extra" was not certainly distinguishable from the two members of pair no. 12. The great similarity of pairs 14, 15, and 16 made it difficult to determine which of them was represented singly. It is considered most likely to be no. 15, and accordingly what is believed to be the extra chromosome is placed beside a single "chromosome 15" in fig. 3.

Interpretation

On present knowledge it is difficult to believe that there might be a genetic mechanism causing mongolism that did not involve the presence in triplicate of at least the greater part of chromosome 22. The clinical diagnosis of mongolism in the present case is undoubted, and it is therefore reasonable to suppose that the "extra" chromosome is compounded of the greater parts of the missing chromosome ?15 and of the expected additional chromosome 22. The literature of cytogenetics does not support the possibility of a permanent end-to-end fusion of two chromosomes, such as these, by their short arms (v. i.). Therefore, the most likely interpretation of the finding is an unequal reciprocal translocation between chromosomes ?15 and 22 with both points of exchange close to the centromere (fig. 4). The morphology of the "extra" chromosome is entirely in accord with this interpretation. The long arm corresponds in length to the long arm of a chromosome 15, and the short arm to the long arm of a chromosome 22.

Since the distinction between the pair of chromosomes 12 and the extra chromosome is uncertain, the cytological evidence alone does not exclude trisomy of chromosome 12 combined with monosomy of chromosome ?15 as the explanation. However, the hypothetical combination in one individual of viability of a monosomic condition and of mongolism originating through a chromosomal mechanism entirely different from the one demonstrated hitherto is considered to be so highly unlikely as to justify rejection.

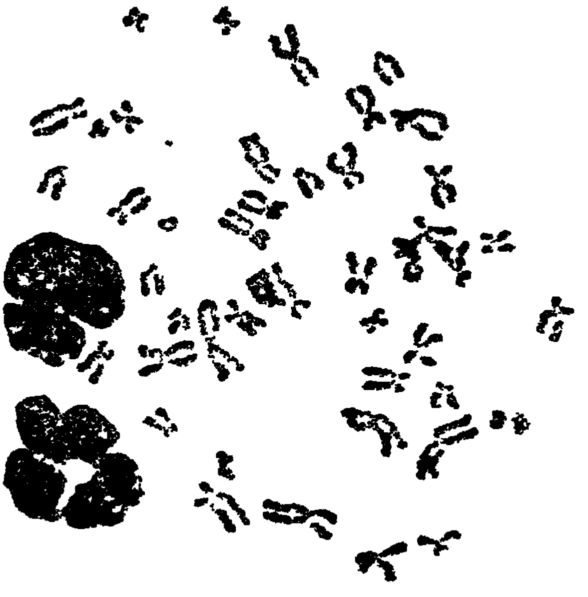

Fig. 2—Chromosomes in a bone-marrow cell.

An alternative mechanism by which mongolism might come to be expressed in an individual with 46 chromosomes is through the origin of an *iso*chromosome from the long arm of chromosome 22. These abnormal chromosomes arise very rarely by *misdivision* (Darlington 1939, 1940) at mitosis or meiosis: that is, the centromere divides transversely instead of equationally, yielding two symmetrical, but genetically unequal, products, each being a duplication of one arm of the original chromosome. Since isochromosomes are, by definition, symmetrical about their centromeres, this explanation is excluded in the present case.

Origin of the Defect

There are five formal possibilities of the origin of such a translocation, two somatic, two germinal, and one which is both germinal and somatic. It may have taken place (1) during embryogenesis from a zygote with a normal complement of 46 chromosomes, or even locally in the bone-marrow after embryogeny was complete, (2) during embryogenesis from a zygote with the 47 chromosomes usual in mongolism, or again at a later stage locally in the bone-marrow, (3) during gametogenesis in one of the parents, (4) during embryogenesis in one of the parents with consequent involvement of all or part of one or both gonads, (5) during embryogenesis or gametogenesis of one of the four grandparents.

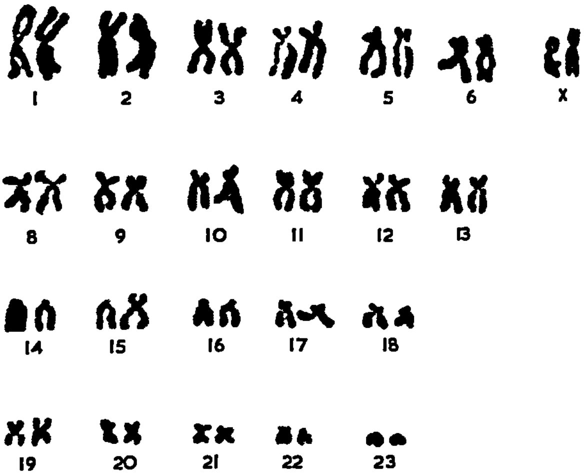

Fig. 3—Idiogram of chromosomes.

The first possibility could only come about as a consequence of a rearrangement (a symmetrical chromatid interchange) occurring after the chromosomes had reproduced in preparation for the next anaphase separation.

This restriction does not apply to the second possibility: the observed abnormality could be derived from a 47-chromosome mongol complement by rearrangement either *before* or *after* chromosome reduplication. In either case, however, the loss of the smaller of the two products of the rearrangement would be necessary to yield the observed set of 46 chromosomes.

If the first cleavage division is excluded, both possibilities, whether occurring early or late in development history and whether locally in bone-marrow or elsewhere, would lead to chromosomal mosaicism (i.e., the presence in the body of two types of cell differing in chromosome constitution). In view of its wide regional distribution, the looseness of its structure, and the ready migration of stem cells from one region to another, bone-marrow is the tissue par excellence in which chromosomal mosaicism (if present) might be detected. The observations give no hint of it.

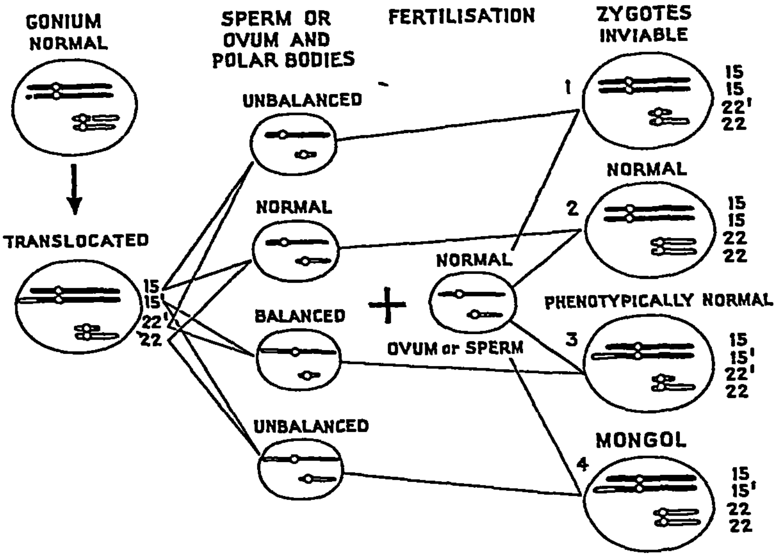

Fig 4—Diagram showing suggested origin of the translocation and its genetic consequences

For illustration, the translocation is shown as having occurred in a spermatogonium or oogonium In the latter case, only one of the meiotic products becomes a functional gamate, the others become polar bodies If the translocation originated earlier in development, the change would be propagated at each mitosis and more gonia would be affected in the same way The exact positions of breakage cannot be defined and the points indicated have been chosen arbitrarily

Offspring

1 is a chromosomally unbalanced (presumably) inviable zygote

2 is normal, phenotypically and chromosomally

3 is chromosomally balanced, phenotypically normal He is chromosomally distinct and will produce the same types of gametes and offspring as the affected parent

4 is a mongol like A

There are also the morphological consequences of postulates 1 and 2 to consider A mosaic of the first type would be genetically normal in part of the body Some hint of regional difference might therefore have been detected at clinical examination—such as the absence of the usual stigmata of mongolism on one hand or foot. The second case is different Both components of the mosaic would, by hypothesis, contain the chromosome material necessary for the expression of mongolism, and morphological indications of mosaicism would not be expected Although neither of the two mosaic possibilities can be rigorously excluded on the present evidence, neither is likely

The third and fourth possibilities differ principally in their genetic implications and both could apply to *either parent* If the translocation had occurred in a single primary spermatocyte or oöcyte, then at most two gametes would have carried the rearranged chromosome and both would have been shed together But it is equally possible that the translocation took place during embryonic development of one parent, or even later, and that several, many, or even all gonia are affected The parent would then be a gonosomic mosaic, a "name used for cases where mosaicism is due to a difference in genetical (*or chromosomal*) constitution between all or part of the soma and all or part of the gonads" (Sidky 1939–40)

The fifth possibility is that, in origin and chromosomal make-up, one of the parents of A may be similar to the "phenotypically normal" zygote mentioned above (see fig 4, zygote 3) The distinct chromosomal make-up would exist both in the gonia and in the somatic tissues, and the hypothesis can be tested by studying the somatic chromosomes of the parents

The cytogenetic behaviour of reciprocal translocations at gametogenesis is well known in other species In man gametes of four principal types would be formed in nearly equal numbers In the present case, assuming that both gonads are wholly affected (and neglecting some rarer types of abnormal gamate), one-quarter of the offspring will be mongols, one-quarter normal, one-quarter phenotypically normal (but chromosomally distinct and reproductively like the parent), and one-quarter of the zygotes produced will be inviable (fig 4) From a genetic standpoint, the last class (fig 4, zygote 1) would be practically monosomic for chromosome 22 The most obvious outward manifestation of the last three possibilities would be a sibship and/or family concentration of mongols

In the present instance, we have no reason for preferring either hypothesis 3, 4, or 5, nor for assigning the origin of the defect to either parent

The present finding of a different chromosome constitution and hence a different mechanism for mongolism may be a sporadic chance happening, and if so is of limited interest However, the manner in which the patient was selected suggests that this is not so—in which event the conclusion would be not only that different chromosome mechanisms may underlie mongolism but also that the condition may be brought about as a consequence of different causal factors operating (on either parent) before conception

This is the second instance of a presumptive translocation to be reported in man Turpin (1959) and Lejeune (1959) found only 45 chromosomes in dividing cells of three independent tissue-cultures established from fascia lata of a boy with multiple abnormalities of the spine —a condition described as *polydysspondylie* A single apparently rearranged chromosome was present that was similar to the one identified here, but there were only three instead of four short acrocentric chromosomes Turpin et al ascribed their rearrangement to a translocation of the greater part of chromosome V_S (23) on to the long arm of T_2 (15) It is remarkable that, in both these presumptive translocations in man, the exchange appears to have taken place between a long and a short acrocentric chromosome Furthermore, all the four breaks that must be postulated evidently occurred close to the centromere—two in chromosome no 15 and one each in no 22 and no 23 This suggests that certain chromosome regions may be specially favoured for participation in chromosome rearrangement, but a departure from randomness could also arise secondarily as a consequence of differential survival at the cellular or zygotic level The chromosomes of pair no 22 bear satellites on their short arms close to their centromeres, so also do two of the long acrocentric chromosomes—either the longest pair (Tjio and Puck 1958) (no 14) or the second longest pair (Chu and Giles 1959) (no 15) It follows that three of the four breaks may have occurred in the neighbourhood of a satellite The fact that Levan and Hsu (1959) have found nucleolar remnants attached to one of the satellited chromosomes supports the assumption that in man, as in other organisms, the "stalk" which attaches satellite to main chromosome body is the site of a nucleolar organiser Nucleoli are formed independently in telophase but are frequently reduced by fusion to a single one by interphase Hence the satellited chromosomes, and particularly the regions adjoining the nucleolar organisers, would tend to lie near one another Close association between points of breakage favours the occurrence of chromosome rearrangements (such as reciprocal translocations), and a nucleolar organiser therefore might well influence the probability that structural changes will take place in its vicinity (Darlington 1939), while there exists the possibility of increased tendency to breakage (or reduced restitution) in this neighbourhood (Darlington 1937, Swanson 1958)

The presence of a nucleolar organiser on pair no 22 may be important in a different way and relevant to the origin of "regular" mongolism Persistence of nucleolar remnants in meiotic prophase may interfere with the approach and pairing of these two short chromosomes (Darlington 1937) to such a degree that no chiasma is formed (Darlington 1935, Upcott 1936) They would then enter the first meiotic spindle as unpaired bodies (univalents) and assort at random to the poles, so yielding gametes in the proportions 2 normal, 1 nullo-22, 1 duplex-22 The other satellited chromosome (no ?15) is at least twice as long as chromosome no 22, and interference of pairing through the same mechanism of nucleolar interference would not be expected to be so severe, if, indeed, it occurred at all

If this analysis is correct, two conclusions follow (1) the primary event (failure of chromosome no 22 to pair) would be four times as frequent as mongolism itself and (2) two chromosomes no 22 would be inherited from the one parent without crossing-over having occurred between them—an eventuality that perhaps will be testable in the far future of human cytogenetics

One further and final point can be made that they may have a bearing on the relationship of mongolism to advancing maternal age It is generally accepted that all primary oöcytes are differentiated before birth, or at latest very shortly afterwards The nucleoli in the oöcytes of a 45-year-old woman would therefore have been in existence for 45 years, and it is conceivable that, in consequence of some progressive biochemical change, they would be more resistant to the normal nucleolar breakdown processes that take place in meiotic prophase Spermatogenesis presents a sharp contrast there is no reason to suppose that any primary spermatocyte has a life longer than a week or two, so that nucleolar breakdown would be expected to proceed at normal rate and not interfere with meiotic pairing

Summary

A mongol girl, selected because she was born from a young mother, in contrast with reported chromosome findings in mongols, had only 46 chromosomes in her bone-marrow cells and had four small acrocentric chromosomes like normal females There were only 5, instead of 6, of the longer acrocentric chromosomes (pairs 14, 15, or 16) but an extra chromosome was present that was not certainly distinguishable from chromosome 12, and this may have carried the major part of the genetic material of chromosome 22

A reciprocal translocation between chromosomes ?15 and 22 is suggested as the origin of the anomaly The possibility that it originated during the development of the patient herself is unlikely but not excluded It is more likely to have occurred in one of the parents, or even a grandparent, possibly during development If one parent were affected, he or she would be a gonosomic mosaic, and there would be an increased probability of further mongol births, as well as other familial and genetic implications Were one of the grandparents affected, the genetic implications would be the same, but one of the parents would be distinct in his or her somatic (and germinal) chromosomal make-up

SOME mongol patients of each sex have a somatic cell complement of 47, instead of the common 46 chromosomes, and morphological evidence indicates that it is one of the small acrocentric autosomes which is triplicated in the diploid complement (Book et al 1959, Ford et al 1959, Jacobs et al 1959, Lejeune et al 1959)

If non-disjunction at parental gametogenesis is responsible for the trisomy in mongol patients it must occur with a relatively high frequency The incidence of mongolism at birth is difficult to assess, but has been generally estimated as more than 1 in 1000 births (Book and Fraccaro 1956) The screening of a large number of patients with detailed study of their chromosomes should indicate whether it is likely that all the cases actually have trisomy

In this paper we describe a mongol boy whose cultured mitotic somatic cells displayed a complement of 46 chromosomes This chromosome number was at first interpreted as the product of a translocation between 2 of the acrocentric chromosomes usually present *in* triplicate in mongolism At subsequent examination of the parent's karyotypes it was, however, found that the mongol's father had 47 chromosomes and was probably trisomic for pair no 19 (Pending agreement on classification we adhere to our provisional system The chromosome present in triplicate in mongolism is in this system no 21)

Case-record

S is a boy born on June 29, 1959, weighing at birth 4560 g The mother, who was 37, had an uneventful pregnancy and no history of irradiation of the pelvic region She had had four other pregnancies resulting in the birth of three normal females

(1941, 1945, 1950) and one normal male (1952), all weighing over 4000 g

S was diagnosed neonatally as a mongol and admitted to an institution for defective children At examination at the age of 5 months (fig 1) the following were noted flat face with squat nose and oblique palpebral fissures, protruding lower lip, and slightly fissured tongue with enlarged papillæ, evident palmar transverse fold on hands, iliac index 43°, a value which is considered below the normal range and typical of mongolism (Caffey and Ross 1956), distinct systolic murmur It was not possible to determine his mental status The father, a minister of religion, was 58 at the birth of S He has no noteworthy history of illness and appears to be in good health

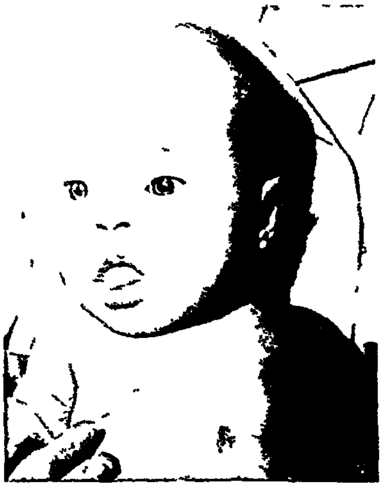

Fig 1—Appearance of the mongol patient

Cytological Observations

Chromosome Number

Bone-marrow and skin biopsies were obtained from S, a skin biopsy from his father, and a bone-marrow punctate from his mother The cells were cultured in vitro and handled according to the technique of Fraccaro et al (1960a) Chromosome counts were performed on both primary and transferred cultures The results are summarised in the accompanying table The chromosome number was 46 both in S and in his mother and was 47 in his father

Karyotype of S

Microscopic examination of more than 60 mitotic cells and detailed analysis of 6 cells (3 from bone-marrow and 3 from skin) by the study of enlarged photomicrographs showed only 4 short acrocentric chromosomes, 1 of them being easily identified (by appearance and arm measurements) as the Y chromosome 5 chromosomes in the small-size range with submedian centromere were found instead of the 4 normally present.

The chromosomes of pairs nos 19 and 20 are normally difficult to identify By arranging them with respect to total arm length *and* centromere position (arm ratio) it is possible, however, to pair off 2 chromosomes with slightly higher arm ratio and total length. In the same way we first "classified" the "5th" chromosome by labelling as such the longest one The mean length (in arbitrary units) was 1 12 and 1 04 for nos 19 and 20 and 1 24 for the "5th" chromosome The mean arm ratios (the long arm divided by the short) were 1 28, 1 21, and 1 18 respectively At this stage of the analysis (before knowing the father's karyotype) we thought that the "5th" chromosome was the product of a reciprocal translocation between two of the triplicated no 21 chromosomes Fig 2, composed at this stage, shows the "5th" chromosome (indicated by an arrow) placed according to this interpretation

RESULT OF CHROMOSOME COUNTS

Individual	Type of culture	Chromosome no ≤43	44	45	46	47	Total
S	*Bone-marrow*						
	Primary	8	3	3	21		35
	1st transfer				5		5
	Skin						
	Primary	2	3		25		30
Father	*Skin*						
	Primary					2	2
	1st transfer	2	2	1	3	19	27
	2nd "	1	1			8	10
	3rd "		1	1	1	14	17
	4th "				1	1	2
Mother	*Bone-marrow*						
	Primary	1			22		23

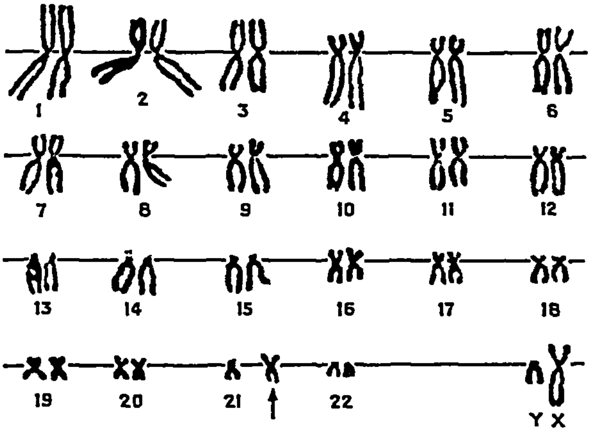

Fig 2—Karyotype of the mongol boy 46 chromosomes (arranged from a mitotic skin cell)

We had little doubt that the odd short chromosome actually belonged to the pair no 21 It was thus identified because both its mean length (0 85) and arm ratio (3 17) were greater than those of pair no 22 (0 77 and 2 44 respectively) Moreover, in good preparations, we found only 1 short acrocentric chromosome displaying satellites, while we usually observe 2 such chromosomes in normal karyotypes and 3 in mongols with 47 chromosomes (Böök et al 1959)

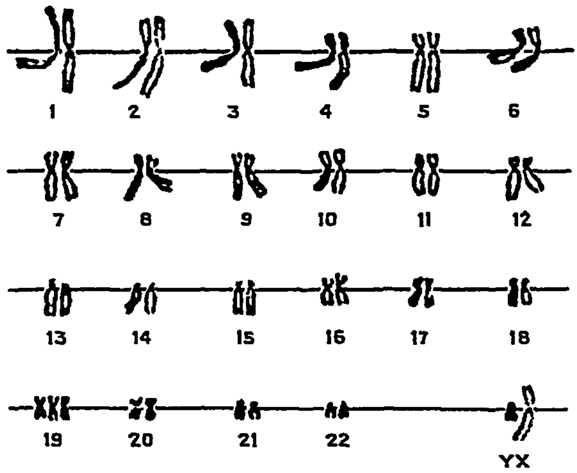

Fig 3—Karyotype of the father 47 chromosomes (arranged from a mitotic skin cell)

Karyotype of S's Father

Detailed analysis of 8 mitotic cells showed that the 47th chromosome was small with a submedian centromere In nearly all the cells counted it was possible to recognise 5 such chromosomes The 47th chromosome was classified on morphological grounds as homologous to those of pair no 19 and it was tentatively concluded that the father was trisomic for this chromosome The chromosomes of fig 3 are arranged according to this interpretation.

Karyotype of S's Mother

All evidence indicated an apparently normal female karyotype

RELIABILITY OF THE OBSERVATIONS

There was no evidence for mosaics of two-cell types In the case of S's father in 2 of the 4 cells with a count of 46 chromosomes it was possible to identify five short submedian chromosomes, in the other 2 the chromosomes were very spread, as in the 3 cells with a count of 45 chromosomes in the case of S

Our observations are based on cells isolated from the donor's body and allowed to divide mitotically in vitro Whether the abnormalities are produced by some factor(s) inherent in the cell culture methods can be determined on indirect evidence Cell populations in vitro undergo changes in metabolic patterns, nutritional requirements, and chromosome number Open system-fluid medium cultures, however, have been recently found to favour karyotype constancy for remarkably long periods (Tjio and Puck 1958, Fraccaro et al 1960a) When cells of different origin are cultured—e g, bone-marrow and skin—and both present constancy and equality of karyotype in primary and transferred cultures, it is reasonable to assume that the abnormalities observed have not primarily arisen in vitro S's cells fulfilled these requirements From S's father only skin cells were cultured and they showed karyotype uniformity and constancy through 4 transfers

If mitotic non-disjunction takes place in vitro the resulting abnormal cells may have selective advantages over the others In our experience, however, based on the examination of cultured cells from some 60 individuals we found no evidence of abnormalities arising in vitro, and karyotype constancy has been the rule for normal and abnormal karyotypes The only exception was found in a presumptive mosaic of bone-marrow cells with both 45 and 46 chromosomes In this case evidence indicated that the "normal" cells with 46 chromosomes had a selective advantage during successive transfers (Fraccaro et al 1960b)

Our results fulfil the requirements of concordance between cells of different origin and uniformity and constancy of karyotype from primary cultures through transfers, and we are therefore inclined to believe that the chromosome abnormalities are characteristic of the individuals

Interpretation and Discussion

Trisomy in man has so far been found only in individuals with pathological phenotypes The possibility exists that S's father is a mosaic of normal and trisomic cells and that the skin cells cultured have been sampled from the trisomic sector But if S's father is trisomic for chromosome no 19 it follows that trisomy does not necessarily involve pathological manifestations This might be explained by the assumption that one of the 2 chromosomes is genetically inert as are generally the supernumerary (accessory) chromosomes found in some plant and invertebrate species which are, however, by definition non-homologous to those of the normal complement These chromosomes are in some animals present in the gonads but inconstant or absent in the somatic cells of adult individuals, and they are generally heterochromatic (Melander 1950)

The report by Kodani (1958) of supernumerary chromosomes in meiotic metaphases in human testes indicates that a similar situation may exist in man The 47th chromosome in S's father is apparently homologous and constant and is therefore unlikely to be a supernumerary chromosome No heterochromatic chromosome of this size was found in preparations stained by Feulgen's method nor were characteristic heterochromatic bodies observed in resting nuclei, which were uniformly sex-chromatin negative

We may interpret the situation in S in two alternative ways

1 The "5th" submedian short chromosome is homologous to pair no 19—i e, S is trisomic for chromosome no 19, *having received 2 such chromosomes from the father and 1 from the mother* In this case he must be monosomic for pair no 21

2 He has received from the father only 1 chromosome no 19, and the "5th" chromosome has been produced by a reciprocal translocation between two chromosomes no 21 with subsequent loss of the other complementary chromosome.

In both cases an error in the division of chromosomes no 21 must have taken place in either parent's gametogenesis or during his embryonic development

The total length of the "5th" chromosome is nearly twice that of the long arms of no 21 By this criterion the hypothesis of a reciprocal translocation between the 2 acrocentric chromosomes (a situation sometimes called a "centric fusion" [White 1954]) seems likely On the other hand, arm measurements cannot exclude trisomy of chromosome no 19 Because of its mean arm ratio above unity the 5th chromosome is unlikely to be an "isochromosome" These are chromosomes with median centromeres, produced by the duplication of one chromosome arm following a transverse division of the centromere

It was therefore concluded that it was not possible on morphological evidence to decide between hypotheses (1) and (2) If hypothesis (1) is correct S is trisomic *and* monosomic for two different autosomes (The monosomic may have originated from failure of chromosome no 21 to pair at paternal meiosis) Trisomy and monosomy in the same individual has been considered very unlikely but it has been reported in two cases of mongolism with 46 chromosomes (Book 1960) It can also be postulated that certain individuals, because of their genetical background and/or because of particular environmental conditions, have a tendency to a "lability" at mitosis or meiosis during their embryonic development or gametogenesis S's father could be such an individual If hypothesis (2) is correct, reciprocal translocation may occur also between homologous chromosomes The two known instances of translocation in human material were between non-homologous chromosomes (Turpin et al 1959, Polani et al 1960) Chromosomes no 21 are satellited and the nucleolar organisers may lie in vicinity during interphase—a condition which may favour the occurrence of structural changes between them (Polani et al 1960)

The phenotype of S can be explained in the case of hypothesis (1) by the assumption that genes located on the single chromosome no 21 manifest themselves since they are in a hemizygous state Under hypothesis (2) S has the greatest part of 3 chromosomes no 21—a sufficient condition for the phenotypical presence of mongolism, in keeping with the observation by Polani et al

We have at present no evidence for preferring either of these two hypotheses We can only reasonably assume that the defect in S is related to the chromosomal anomaly found in the father The examination of the four apparently normal sibs of S may reveal whether some of them are also trisomic for chromosome no 19, and we hope to obtain biopsy material in the near future

Different causal factors may have produced the trisomy in the father These are those commonly said to account for chromosomal anomalies in man (Polani et al 1960)

Summary

In the case of a mongol boy the somatic cells had 46 chromosomes, in contrast to the 47 commonly found in mongolism

The mongol's father, an apparently healthy man, was found to have 47 chromosomes in skin cultures In the mongol there were only 4 short acrocentric chromosomes, instead of 5, but an extra chromosome was present that was similar to those of pairs nos 19 and 20 In the father the 47th chromosome was similar to those of pair no 19

The father is probably trisomic for chromosome no 19 The mongol may be trisomic for chromosome no 19 *and* monosomic for no 21, or else the extra chromosome may be the product of a reciprocal translocation between 2 chromosomes no 21 It is not possible, on the evidence available, to decide which hypothesis is correct

The findings show that fertile, clinically healthy individuals may have a chromosome anomaly and that mongolism may arise from chromosome situations other than the trisomy of chromosome no 21

This research has been aided in part by a grant from the Swedish Cancer Society to one of us (M. F)

THE standard manual methods of artificial respiration without an artificial airway do not move a tidal volume greater than the victim's dead space in 25–80% of cases (Gordon et al 1958, Safar 1959), and there is clearly a need for a more efficient method. Expired-air resuscitation has been proposed as such a method, and several reports (Elam et al 1954, Greene et al 1957, Safar et al 1957) indicate that this is indeed efficient. All workers agree that a trained operator can move tidal volumes in excess of 1 litre with every breath, and it has been claimed that the method is easily taught (Safar 1958, Dobkin 1959)

As its use in the Royal Navy was to be considered, and as practical experience of it in Britain was sparse, the method was studied further

Methods

Twenty-two anæsthetised and paralysed patients undergoing elective surgery were used. Their tidal volume, minute volume, and end-tidal CO_2 tension were measured, and so was the donor's end-tidal CO_2 tension. Oxygen saturation was not measured, as all workers agree that it remains satisfactory during expired-air resuscitation if adequate minute volumes are maintained. Since it has been shown (Nunn 1958, Ramwell 1958) that under the conditions of this study there is a fairly constant relationship between arterial and end-tidal CO_2, it was not thought necessary to make direct measurements of the arterial CO_2 tension.

Choice of patients was limited to those who showed no evidence of respiratory disease, so that, firstly, the end-tidal P_{CO_2} would be a good measure of $PaCO_2$, and secondly there would be less likelihood of any postoperative respiratory complications, for which the expired-air resuscitation would undoubtedly have been blamed Operations on the head, neck, thorax, and upper limbs were excluded as the donor and equipment would have been too close to the operative field Upper-abdominal operations in which either large diaphragmatic excursions or possible gastric distension would interfere with the surgery were also excluded.

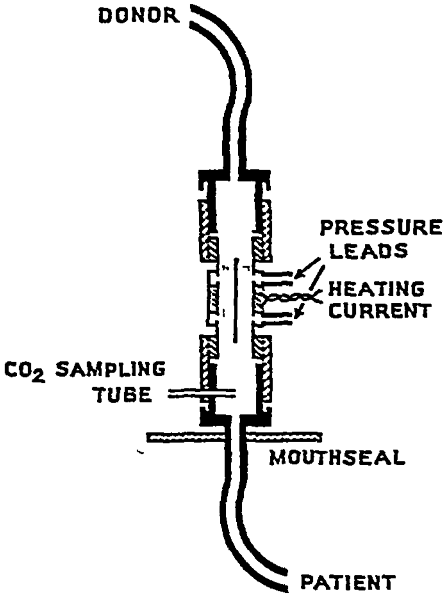

Fig 1—Double airway and pneumotachograph head.

The mouth-to-airway method (Safar 1958) was used rather than the direct mouth-to-mouth, to facilitate measurement and to avoid æsthetic objections Considerable difficulty was experienced at first in maintaining an adequate mouthseal and several types were tried. The most satisfactory, suggested by Mr D Hill, consisted of an oval, 5×2½ in., of soft $^1/_{16}$ in. rubber sheet with $^1/_4$ in. foam plastic glued on to one surface The foam plastic formed an airtight joint between the patient's face and the rubber

A pneumotachograph head (Fleisch 1925) was interposed between the two halves of the double airway, whose volume was 31 ml. (fig 1) The pressure drop across it was measured by a differential capacitance manometer The output from this was integrated electrically and recorded by a pen oscillograph. After calibration tidal volumes could be read directly from the tracing The screen of the pneumotachograph head was heated electrically to prevent condensation of water altering its resistance Baseline drift, due to inequality of inspired and expired gas volumes because of diffusion, departure of the respiratory quotient from unity, or leaks at the mouthpiece, was offset electrically The recording equipment is shown diagrammatically in fig 2, and pictorially in fig 3

Continuous analysis of carbon dioxide was carried out from a sampling-point just distal to the pneumotachograph head (fig 1) using a rapid infra-red analyser (White 1958) Its output was fed on to the second pen of the oscillograph.

Calibration

Tidal-volume recorder.—Air was passed through the pneumo-

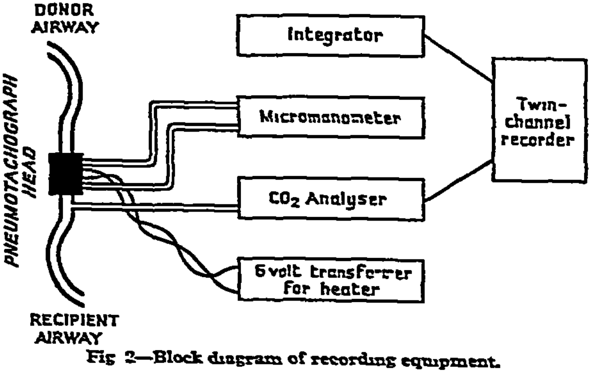

Fig 2—Block diagram of recording equipment.

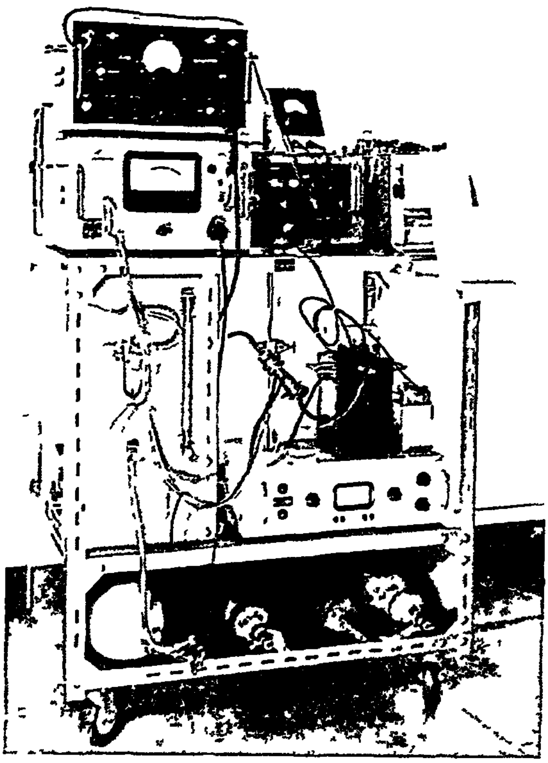

Fig 3—Recording equipment on trolley.

tachograph head at different flow-rates, which were measured by a rotameter, and the output of the capacitance manometer was fed directly (i e, without integration) to the oscillograph The gain of the oscillograph amplifier were held constant and the paper speed was checked against an oscillator The numerical relationship between the gas-volume passed per unit time and the area below the trace was calculated from this This area was obtained by counting squares or (later in the study) by planimetry The electrical integrator was then put into circuit, its ability to perform this calculation accurately at various gas-volumes and flow-rates was checked, and the relationship between the peak height of its tracing and the patient's tidal volume was calculated The output voltage of the integrator had previously been shown to be a linear function of tidal volume, using a sine-wave pump of variable stroke-volume and rate

Carbon dioxide—Three calibrating mixtures of CO_2 in oxygen, covering the expected range, were used Their exact composition was determined by the method of Scholander (1947) The deflection of the galvanometer of the CO_2 analyser for each of the three concentrations, and for zero, was plotted and a calibration graph was constructed During use the analyser was frequently calibrated with one of these mixtures Before use the instrument was allowed to warm up for at least three hours

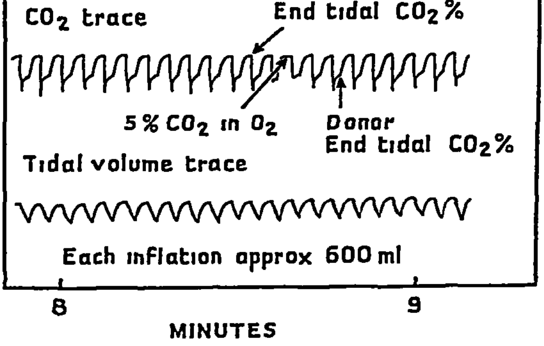

Fig 4—Record from a typical case

Errors—The error due to calibrating with dry air, rather than moist expired air, is undetectable with the system used (Newman 1958) There was no detectable alinearity in the pneumotacograph-manometer-recorder system at gas flows of up to 100 litres per minute The error in calibrating with carbon dioxide in oxygen instead of in air is of the order of 0 1% v/v over the range of carbon-dioxide levels encountered (Hill 1957)

Results

The twenty-two patients were ventilated by expired-air resuscitation for periods varying from fifteen minutes to one hundred and fifteen minutes Eight donors were used, none of whom had performed expired-air resuscitation previously .In no instance was difficulty experienced in inserting the airway and starting resuscitation

Fig 4 shows a typical example of the tracings obtained, fig 5 shows the results in one case presented graphically, and in fig 6 the results of all the cases are charted The general condition of all patients remained good during expired-air resuscitation There was no evidence of hypoxia In two cases there was obvious gastric distension One patient complained of a sore nose postoperatively, and one sustained a bruised lip

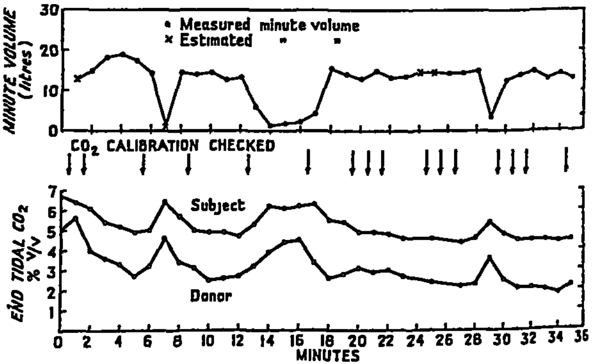

Fig 5—Graphic presentation of results in one case

In all cases except the second, in which the carbon-dioxide analyser gave trouble, it was shown that the patients' end-tidal carbon-dioxide concentration could be maintained below 5 6% with ease The patients' (and donors') end-tidal carbon-dioxide concentration varied with the minute volume, the critical level of which appears to be in the region of 10 litres Elam et al (1958) pointed out that the donor must hyperventilate and suggested a minute volume of 10 litres on theoretical grounds

The commonest symptom in the donor was tired hands from maintaining the airway and the mouthseal The easiest way of doing so was for the donor to hold the patient's head extended with the chin up, using the hypothenar part of the palm and the fourth and fifth fingers of one hand The thumb and second and third fingers of the same hand pressed the mouthseal to the patient's face The nose was occluded with the other hand (fig 7) Apart from tired hands the major factor limiting the time a donor could maintain expired-air resuscitation (excluding the length of the operative procedure) seemed to be boredom, there was certainly no general fatigue Other symptoms in the donors included dizziness, but at no time was this sufficiently severe to cause them to give up resuscitation It was not obviously correlated with any

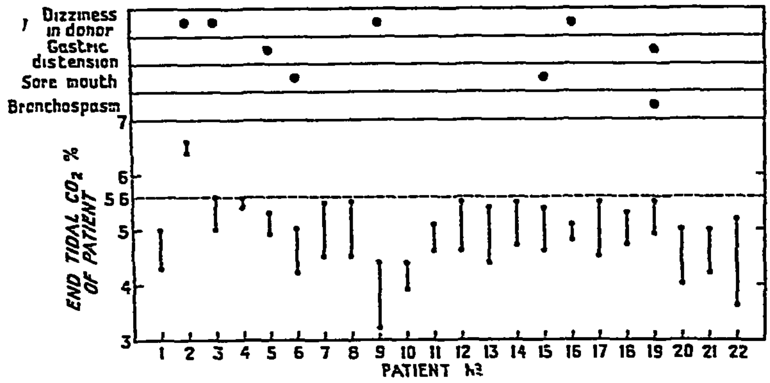

Fig 6—Results in all cases

definite levels of end-tidal carbon-dioxide concentration. Of the four donors whose end-tidal carbon-dioxide concentration fell below 2%, only one felt dizzy, and one other experienced tingling in the lips. On the other hand one donor felt dizzy with an end-tidal carbon-dioxide concentration of 2·75%. One donor complained of "popping" of her ears with each inflation. No other symptoms were recorded.

Discussion

The criticisms that have been levelled at expired-air resuscitation include the following (1) æsthetic objections, (2) production of gastric distension, (3) possible lung rupture, (4) cross-infection between recipient and donor, (5) possible circulatory effects of intrathoracic positive pressure, (6) inadequate carbon-dioxide elimination in the subject, (7) hypocapnia in the donor.

Æsthetic Objections

We consider that these are considerable in mouth-to-mouth resuscitation, except possibly in the case of infants. For this reason we have adopted the mouth-to-airway method.

Gastric Distension

This, when it occurs, is of considerable importance in infants, in whom it may lead to a raised diaphragm and decreased venous return. Consequently in infants pressure should be maintained on the epigastrium with one hand during expired-air resuscitation. In adults, however, it does not seem to matter. With visible epigastric distension, Safar (1958) never found more than 1900 ml. of air in the stomach, and in these cases no alteration in the pulse-rate or blood-pressure was noted.

Morton and Mushin (1958) have shown that in anæsthetised and paralysed patients with an unobstructed airway, when the lungs are not held inflated, inflation pressures of 15 cm. of water or less cause no gastric distension. With peak pressures of 20–25 cm. of water, gastric distension occurred occasionally.

Lung Rupture

This is unlikely in adults unless the lungs are grossly diseased. Champneys (1887) found that in dead infants, to produce lung damage by inflation, a minimum of 20 mm. Hg was required. However, Emmert (1930) reported a fatal case of pneumothorax in a newborn infant following mouth-to-mouth resuscitation.

Infection

This is theoretically possible, and indeed Champneys (1887) recorded twelve cases of infants infected by a tuberculous midwife who practised mouth-to-mouth resuscitation. However, it is relatively unimportant when the method is being used in real emergency. When it is being taught on human subjects, a bacterial filter can be inserted if this is thought necessary.

Possible Circulatory Effects

We think that it is better to risk possible circulatory effects with a good tidal volume than to have no adverse circulatory effects from increased intrathoracic pressure and no tidal exchange.

Carbon-dioxide Levels

These are satisfactory in the subjects and tolerable in the donors.

Conclusions

In this study expired-air resuscitation was found to be easy and effective. We consider that the mouth-to-airway method is the one of choice as the æsthetic objections to mouth-to-mouth methods are great. Admittedly this introduces the need for some apparatus, but this is simpler and cheaper than any form of manually operated bellows. In addition a "double airway" has no moving parts or valves to deteriorate during storage—a particular risk in hot climates. The method was found to be easy to teach to untrained subjects.

Summary

Mouth-to-airway expired-air resuscitation was studied in twenty-two patients. Minute volumes achieved, and patients' and donors' end-tidal carbon-dioxide levels, were measured.

This is an effective method of resuscitation.

The method should take its place as an alternative to the standard methods, to which it is in some cases to be preferred.

We should like to thank the Medical Director-General of the Navy for permission for Surgeon Lieutenant-Commander Cox and Sick Berth Petty Officer Thomas to participate in this study, members of the staffs of the Middlesex and the Whittington Hospitals for their help and for allowing us to study patients under their care, and Mr Dennis Hill and Dr J. F. Nunn, who gave considerable help and advice throughout the study.

THE MUCOSA OF THE STOMACH AND SMALL INTESTINE IN IRON DEFICIENCY

ANNETTE RAWSON
M B Lond , M R C P
MEDICAL REGISTRAR

F D ROSENTHAL *
M D Lond , M R C P
SENIOR NEUROLOGICAL REGISTRAR

THE QUEEN ELIZABETH HOSPITAL, BIRMINGHAM, 15

DEGENERATIVE changes in the epithelial tissues of patients with iron-deficiency anæmia have long been recognised, and of these koilonychia, angular stomatitis, and glossitis are relieved by iron therapy Hypochlorhydria or achlorhydria, with varying degrees of chronic gastritis and gastric atrophy, are common (Witts 1930, Davidson and Markson 1955) Davidson and Markson (1955) and Badenoch et al (1957) regarded them as the result of iron deficiency, but Lees and Rosenthal (1958) found that, when this was corrected, the gastric mucosa did not improve, and concluded that the gastric lesions preceded and favoured its development

There have been few reports on the appearance of the small-intestinal mucosa in iron deficiency (Doniach and Shiner 1957, Shiner 1958) We decided to ascertain whether there were any histological abnormalities of the mucosa of the upper small intestine, or any abnormalities of small-intestinal function Any changes would, we thought, be of considerable interest, but the finding of normal mucosa in the small intestine would strengthen the view that iron deficiency is chiefly due to abnormalities in the gastric mucosa and its secretions

Ten patients (see table) were selected on the following basis

1 A fasting serum-iron level of less than 40 μg per 100 ml
2 Absence of demonstrable gastrointestinal ulceration or bleeding
3 Freedom from disease known to be associated with disturbances in iron metabolism
4 Correction of the anæmia by oral iron alone

Biopsies

The small-intestinal mucosal specimens were obtained with a Shiner intestinal biopsy tube (Shiner 1956) At least four specimens were obtained from the small intestine proximal to the ligament of Treitz When possible a gastric specimen was obtained at the same time, but in five cases the gastric biopsy was undertaken a few days later with a Wood's biopsy tube Techniques were essentially as described by Shiner (1956) and by Wood et al (1949) Specimens were fixed in formol-saline and sections were stained with hæmatoxylin and eosin. Terminology and analysis of the gastric mucosa is that of Lees and Rosenthal (1958) superficial and deep infiltration with inflammatory cells was classified as minimal, mild, moderate, or severe, while atrophy was graded as mild, moderate, severe, or complete

Augmented Histamine Test-meal

A modification of Kay's method was used (Kay 1953) A radio-opaque Levine tube was passed under fluoroscopic control so that the tip lay along the greater curvature of the stomach at the level of the angulus (It was found that advancing the tube further led to aspiration of duodenal contents) Resting juice was collected by continuous suction for 45 minutes 15 minutes after starting the aspiration 100 mg mepyramine maleate was given by intramuscular injection After collection of the resting juice, histamine acid phosphate 0 04 mg per kg body-weight was injected subcutaneously and the gastric juice was collected by continuous suction for 45 minutes The volume of both specimens was measured, and the acidity determined by titration of 5 ml aliquots against *N*/10 NaOH using Toepfer's reagent as the indicator

Iron Tolerance Test

After an overnight fast, a specimen of blood for serum-iron estimation was obtained with an iron-free needle and iron-free glassware Ferrous gluconate (1 0 g , containing 116 mg elemental iron) as finely crushed tablets was given by mouth, and further specimens for serum-iron estimation were obtained 2 and 4 hours later The serum-iron was estimated by an adaption of the *o*-phenanthraline method (Barkan and Walker 1940)

Serum Vitamin B_{12}

This was assayed with *Euglena gracilis* " Z strain ", by a modification of the Ross's (1952) method

Other Investigations

These include fæcal fat excretion over a 5-day period, a glucose-tolerance test, and estimation of serum-proteins, serum-calcium, serum-phosphorus, and serum-alkaline-phosphatase

Results

Biopsy of small intestine —The histology was considered normal in all ten cases

Biopsy of gastric mucosa —None of the patients had a normal mucosa All showed superficial infiltration (one minimal, two mild, two moderate, and five severe) Nine showed deep infiltration (two minimal, four mild, two moderate, and one severe) Atrophy was absent in one case and in eight cases it was moderate (see table)

Augmented histamine test-meal —In eight cases no free acid was present in the resting juice, in one case a small amount was demonstrated, in one case secretion was within normal limits After histamine stimulation, three cases had an achlorhydria, in five cases small amounts of acid were obtained, and in two cases acid secretion was normal (Kay 1953)

Iron tolerance test —The maximum rise in serum-iron varied between 74 μg and 417 μg per 100 ml

Serum vitamin B_{12} —The serum levels of vitamin B_{12} were within the normal range, except in case 6, where the value was 70 μμg per ml (average of two separate estimations) On treatment of this patient with oral iron, the serum-B_{12} rose to 140 μμg per ml when the hæmoglobin reached 11 7 g per 100 ml

Other investigations —No abnormality in fat excretion, glucose tolerance, or the level of serum-proteins, serum-calcium, serum-phosphorus, or serum-alkaline-phosphatase was demonstrated

Although the presence of gastritis and gastric atrophy seemed to be reflected in the generally small amounts of acid obtained, the appearance of individual biopsies could not be correlated with acid secretion Similarly, no close relation could be established between gastric mucosal appearances or acid secretion and serum-B_{12} levels

The mucosa of the small intestine was normal in all cases

Discussion

Witts (1956) estimated that about 50 g of gastrointestinal mucosa have to be replaced every day, and thought that an adequate supply of iron was required for this loss to be made good Our findings show that the small intestine and its absorptive capacity remain unaffected, even though the mucosa of the body of the stomach may be highly abnormal Such results were not unexpected, since absorption of inorganic iron, and of iron in food, is known to be increased in iron deficiency (Chodos et al 1955)

The part played by abnormality of the gastric mucosa and its secretions in the development of iron deficiency is still controversial (*Lancet* 1958) The lesions have been shown by Davidson and Markson (1955) to be quite nonspecific, though they are much commoner in patients with idiopathic hypochromic anæmia than in people without such anæmia Except in one case reported by Badenoch et al (1957), treatment with iron has not been found to improve the degree of atrophy or gastritis (Davidson and Markson 1955, Baldini and Cheli 1957, Lees and Rosenthal 1958) The gastric mucosal abnormalities seem to be responsible for the high incidence of hypochlorhydria and achlorhydria in iron deficiency, and in our patients the augmented histamine test-meals demonstrate that, even with maximal stimulation, there may be gross deficiencies in the production of hydrochloric acid Badenoch et al (1957) showed that production of pepsin and of intrinsic factor may also be considerably impaired, and in one of our cases the serum-B_{12} level was only 70 µµg per ml

The exact mechanisms by which abnormalities in the gastric mucosa and its secretions might affect the liberation of iron from food and its absorption remain obscure That some gastric factor is at work is suggested by the fact that achlorhydria may precede iron deficiency by up to 20 years (Meulengracht 1932)

It is generally accepted that ferrous ions are more easily absorbed than ferric (Hahn et al 1945) and that ascorbic acid reduces ferric to ferrous ions and prevents the oxidation of ferrous ions (Moore and Durbach 1951) This action of ascorbic acid and other reducing substances takes place more readily at low pH, and gastric hydrochloric acid could influence iron absorption in this way (Bergheim and Kirch 1949) Barer and Fowler (1937) held that absorption of small amounts of iron was reduced in the presence of achlorhydria, but neither they nor Moore (1955) were able to improve absorption by giving hydrochloric acid. Rosenthal et al (1959) could not relate iron absorption, as measured by iron-tolerance tests, to changes in the gastric mucosa Although in the small number of cases in the present series there were signs of a correlation between the maximum rise in serum-iron and the amount of acid secreted after maximum histamine stimulation, further investigations (unpublished) have not confirmed this

However, if the abnormalities of the gastric mucosa and its secretions have a significant influence, this can only be one of several factors Even in idiopathic hypochromic anæmia the gastric mucosa is not uncommonly normal (Davidson and Markson 1955, Badenoch et al 1957) We excluded from our series any case with demonstrable gastrointestinal blood loss, but six of our nine female patients had menorrhagia and in seven of our patients the diet was considered to be iron-deficient. Hæmorrhage and an iron-deficient diet are recognised to be major factors in the development of iron deficiency Gastric secretions can have no influence on the development of iron deficiency in persons with negative iron balance, but failure of these secretions may be important when food iron just suffices to correct iron loss

Summary

1 In iron deficiency the mucosa of the small intestine, and its absorptive capacity, appear to be normal

2 The normal small-intestinal mucosa and its absorptive capacity contrasts with the frequent finding of abnormalities of the gastric mucosa and its secretions

3 The evidence that the gastric mucosal changes are not due to iron deficiency, and that gastric acid may influence iron absorption, is examined The suggestion is made that gastric mucosal abnormalities may be important when intake of food iron is marginally adequate

We wish to thank Prof W Melville Arnott and Dr Gilbert S Hall for kind permission to study patients under their care, Dr J N Marshall Chalmers for hæmatological help and the estimation of vitamin-B_{12} levels, Dr F Neale for the serum-iron estimations, Dr J M French for measuring the fat excretions, and Dr W T Smith for reviewing the histological findings

CHLORAMBUCIL IN ERYTHRODERMIA

JOSEF LIBÁNSKY
M D Charles University
ASSISTANT PROFESSOR AND HEAD OF THE CLINICAL DEPARTMENT, INSTITUTE OF HÆMATOLOGY AND BLOOD TRANSFUSION, PRAGUE

JIŘI TRAPL
M D Charles University
ASSISTANT PROFESSOR, SECOND DERMATOLOGICAL CLINIC, CHARLES UNIVERSITY, PRAGUE

PRIMARY erythrodermia presents a difficult therapeutic problem The relation of this disease to the hæmoblastoses has been known for some time but has rarely been taken into account in seeking the pathogenesis of erythrodermia, and only recently has the number of articles on this subject increased considerably Erythrodermic manifestations are often encountered within the wide framework of the hæmoblastoses of the reticuloendothelial system—particularly in the reticuloses, and less frequently in mycosis fungoides and malignant lymphogranuloma (Degos and Ossipaski 1957) The term erythrodermia is sometimes used for the benign reversible reaction of the reticular tissue (the so-called lipomelanotic reticulosis of Pautrier-Worringer) or for a true proliferation with various degrees of differentiation Erythrodermia thus comprises many different pictures, and evaluation in a given case may present clinical, pathogenetic, and prognostic difficulties Together with skin manifestations there may be (1) involvement of the lymph-nodes (mainly inguinal and axillary) by a hyperplastic or tumorous process, (2) splenomegaly, (3) normal peripheral blood-smears, or (4) blood-smears showing a percentage of monocytoid cells of various differentiation or changes ranging from simple bone-marrow hyperplasia to infiltration by tumorous elements of reticuloendothelial origin

The degree of inflammation of the skin varies, and the skin may be pigmented, irregularly infiltrated, dry, oozing, itching, or burning The symptoms may disappear after some weeks, or they may last for months or even years, causing progressive cachexia, or the course of the disease may be rapid like that of the malignant reticuloses

Until recently treatment has been symptomatic The steroids seemed to offer hope, but they caused only temporary improvement and alleviation of the symptoms

On the assumption that erythrodermias are associated with reticuloses, and especially when there were histological and cytological changes in the lymph-nodes, we tried chlorambucil ('Leukeran'), a modern cytostatic agent which had given good results in the treatment of malignant lymphomas Because the effects were surprisingly good we decided to describe our results so far Moreover, the response to chlorambucil throws light on the pathogenesis of "hyperplastic" erythrodermias by proving their close relation to hæmoblastoses of the reticular system

The Investigation

Four patients were treated with chlorambucil Before and during treatment they were examined in detail, including histology of the skin, full blood-counts and bone-marrow biopsy, cytology of lymph-node punctures, and histology of lymph-nodes, to assess the overall degree of involvement, and to obtain an accurate morphological classification

Case 1—In June, 1957, a tailor, aged 66, started to have violent itching, first of the legs and later of the whole body Treatment with anti-histamines and vitamins gave no relief His skin all became red gradually, with slight infiltration, much pigmentation, and persistent itching, and the axillary and inguinal lymph-nodes enlarged grossly, suggesting erythrodermia

Examination revealed generalised enlargement of lymph-nodes up to the size of a plum, and slight splenomegaly, the liver reached 1 in below the costal margin

Laboratory Studies

The hæmoglobin content was 17 2 g per 100 ml and the erythrocyte-count was 5 million per c mm The white-cell count was 7700 per c mm (neutrophils 60%, eosinophils 19%, monocytes 5%, lymphocytes 16%), and in addition there were 1 5% leucoblasts of malignant appearance, the nuclei of which resembled reticular cells containing 1–2 nucleoli The platelet-count was 160,000 per c mm The smear from bone-marrow aspiration showed mild eosinophilia and sporadic atypical reticuloendothelial-like cells, as in the blood itself

The lymph-node punctate showed distinct proliferation of reticular cells without pronounced malignant changes Histologically the skin presented the picture of reticulosis, with distinct tumorous elements, mitoses, and eosinophils Around the vessels the infiltration reached deep into the corium and subcutis

Plasma-protein electrophoresis revealed albumin 48 6%, α_1-globulin 6 34%, α_2-globulin 11 98%, β-globulin 12 03%, γ-globulin 21 7%, and total albumin and globulin 9 4 g per 100 ml

Response to Therapy

In March, 1958, the patient was given chlorambucil 276 mg (4 6 mg per kg body-weight) in the course of 4 weeks During the following 3 weeks the redness of the skin gradually vanished, the itching ceased, and the skin regained its normal colour Only the inguinal lymph-nodes remained enlarged, and these had become much smaller The spleen was no longer palpable The leucoblasts disappeared from the blood, and the eosinophil-count rapidly became normal The remission after this single dose of chlorambucil has persisted for 24 months

Case 2—A man, aged 60, had had erythrodermia for 8 years He had been treated with corticotrophin, cortisone, and anti-histamines, with only slight temporary improvement

Before he was given chlorambucil his skin was a brownish-red colour, with slight desquamation The lymph-nodes were generally enlarged to about the size of hazel nuts, but the spleen and liver were not palpable

Laboratory Studies

On June 16, 1958, the hæmoglobin was 15 2 g per 100 ml, the red-cell count 4,950,000 per c mm, and the white-cell count 5800 per c mm (neutrophils 66%, eosinophils 8%, monocytes 6%, lymphocytes 20%) The platelet-count, erythrocyte-sedimentation rate, and bone-marrow-aspiration biopsy were within normal limits

Lymph-node biopsy revealed proliferation of reticuloendothelial elements, but the morphological picture did not show clearly whether the reticulosis was benign or malignant Histologically, however, the focal hyperplasia of reticuloendothelial elements resembled a malignant reticulosis, but there was also melanotic pigmentation in view of which the diagnosis of dermatopathic lymphadenitis (lipomelanotic reticulosis) could not be ruled out

Plasma-protein electrophoresis showed albumin 52 6%, α_1-globulin 3 18%, α_2-globulin 7 51%, β-globulin 8 43%, γ-globulin 27 1%, and total albumin and globulin 6 8 g per 100 ml

Response to Therapy

Treatment with chlorambucil was started in July, 1958, and the patient was given a total of 360 mg (5 6 mg per kg body-weight) in the course of 4 weeks The itching decreased during treatment and finally disappeared The skin became pale, only slight redness persisting on the inner aspect of the thighs and on the scrotum The axillary lymph-nodes became normal, and the inguinal and neck nodes diminished considerably in size

After a remission lasting 7 months redness and desquamation reappeared on the nape of the neck and the scrotum, and the inguinal lymph-nodes enlarged to the size of a plum On July 4, 1959, the patient was again admitted to hospital for further treatment with chlorambucil Within 2 weeks of treatment the itching ceased and most of the skin became pale During the next month the improvement continued There remained only slight desquamation on the inner side of the thighs, and slightly enlarged lymph-nodes

After a remission of 3 months his condition deteriorated slightly After a third course of chlorambucil, however, all the symptoms virtually disappeared

Because of these two satisfactory results chlorambucil was given to a third patient with erythrodermia Incomplete remission followed, which we attributed to an insufficient total dose of chlorambucil—the patient having left hospital prematurely After 6 months another course of treatment was given (total dose 360 mg , 4 8 mg per kg body-weight) The skin manifestations improved strikingly As only a short time has elapsed since the end of the treatment this case cannot yet be finally evaluated Chlorambucil was also given to a patient with mycosis fungoides, whose disease originally resembled erythrodermia and had lasted for 18 years The improvement which resulted far surpassed any treatment (steroids, radiotherapy, &c) he had had previously

Discussion

Chlorambucil, p-(di-2-chloroethylamino)-phenylbutyric acid, synthesised by Everett et al (1953) and introduced by Haddow (1952, 1953) for the treatment of neoplastic disease, has proved its worth in malignant lymphogranulomas, chronic lymphatic leukæmias, and some hæmoblastoses of the reticular system (Galton et al 1955, Altman et al 1956, Bernard et al 1956, Bouroncle et al 1956, Ultmann et al 1956) Our own experience (Libansky et al 1957, 1959) has confirmed these findings As far as we know, however, chlorambucil has not been tried previously in the treatment of erythrodermias when the skin manifestations overshadow the changes in lymph-nodes and other organs, or when the skin alone shows evidence of a disease process

According to our concept erythrodermia always represents a proliferation of the reticuloendothelial system, even when it is not secondary to a hæmoblastic process involving the lymphopoietic tissue, as in Hodgkin's disease We believe, therefore, that chlorambucil should be tried even in those cases where erythrodermia is the only clinical and pathomorphological manifestation Chlorambucil was more effective than any other form of therapy (anti-histamines, steroids, vitamins, &c) in patients who had been treated previously Although the number of cases is small and our follow-up relatively short, we thought it desirable to report our results, for any means of alleviating such a chronic and highly irritating disease should be tried Experience with more cases will show whether chlorambucil is a suitable drug for all forms of erythrodermia. In our patients chlorambucil was well tolerated and free from side-effects, but we suggest that patients having this drug should be under observation and their blood-counts should be checked weekly

Summary

Treatment with chlorambucil (' Leukeran ') has been very effective in four patients with erythrodermia

One patient with severe itching, infiltration, and pigmentation of the skin, gross enlargement of the lymph-nodes, and atypical elements in the blood, had a remission after a single dose of chlorambucil which lasted for 24 months

Another patient had a remission for 7 months, after having chlorambucil, and a second course of treatment again gave good results

In two other patients the effect of chlorambucil was very favourable, and superior to all other forms of treatment

In view of our experience so far we recommend chlorambucil for the treatment of erythrodermias

Addendum

After completing this article we gave chlorambucil to another patient, 56 years old, who had very severe manifestations of erythrodermia with much pigmentation and generalised enlarged lymph-nodes On histological examination a significant hyperplasia of reticuloendothelial elements was found The leucocyte-count was raised to 16,000 per c.mm , with eosinophilia and single atypical monocytoid cells in the blood

The symptoms had persisted for a year, and prednisone had given only slight and temporary improvement Chlorambucil (total dose 350 mg , 5 mg per kg body-weight, over 4 weeks) temporarily combined with prednisone caused marked improvement, the oozing ceased, and desquamation and itching diminished The improvement continued for the next 2 months, leaving only slight redness and itching of the thighs The remission has now lasted for 4 months

Preliminary Communication

ANTIBIOTIC ACTIVITY OF HÆMOLYTIC ENTEROCOCCI

STRAINS of β-hæmolytic streptococci of many Lancefield groups produce antibiotic substances under appropriate conditions The organisms shown to be sensitive to these antibiotics are mainly other streptococci [1–3] This communication brings evidence that such inhibitory activity is a common characteristic of certain hæmolytic group-D streptococci and that it is effective against some intestinal anaerobes

The cross-streaking method was used to study the interaction of 19 strains of group-D streptococci with typical examples of the organisms listed in the table The group-D strains consisted of 3 National Collection of Type Cultures (N C T C) strains of *Streptococcus durans* (8129, 8174, 8307) and 16 strains of *Str fæcalis* var *zymogenes* 2 of these were N C.T C strains (5957, 8176), and the other 14 had been isolated from wound exudates and fæcal specimens Apart from 8129 *Str durans*, which was α-hæmolytic, all strains were β-hæmolytic on horse-blood agar

The sensitivity of an organism was tested by first spreading it as shown in the figure, so that the growth density gradually diminished from one side to the other, and then cross-streaking this area with the streptococcus by a single stroke from the

* These included 1 strain of types A–F, 1 heat-resistant strain, and 7 untyped strains of human origin

The facultative anaerobes were tested both aerobically and anaerobically

denser side The plate was incubated immediately thereafter at 37°C and read for inhibition thirty-six to forty-eight hours later

The figure shows a strain of *Clostridium welchii* type A spread in this manner and cross-streaked with the five N C T C strains This plate showed that the two hæmolytic *Str fæcalis* strains and 8174 *Str durans* were active in producing inhibition Organisms sensitive to these strains are listed in the table

Active filtrates were prepared by growing either of the 2 *Str fæcalis* strains for forty-eight hours at room temperature in 20% serum meat-extract broth The cell-free filtrates, when placed in wells made in the plates, inhibited the same range of organisms as the enterococci themselves Controls of the same pH values did not cause inhibition The inhibitory activity was still detectable at least seven days later if the filtrates were kept at 4°C The inhibitory activity was heat-labile (destroyed by an hour at 60°C) Both the organisms and the filtrates produced inhibition on ordinary meat-extract agar and on catalase-rich media such as horse-blood and heated-blood agar 10% hydrogen peroxide controls in the wells produced inhibition on the ordinary agar medium but effervesced and were inactive on the catalase-rich media The filtrates did not effervesce on the catalase-rich media and any hydrogen peroxide present must have been small in amount and easily inactivated

The further 14 strains of *Str fæcalis* var *zymogenes* were tested against a selection of the sensitive and insensitive aerobes and anaerobes listed in the table, and their inhibitory activity in all cases corresponded with that of the N C T C strains

The main interest of these observations lies in the inhibitory effect of the enterococci upon *Cl welchii* Smith [4] mentions this inhibitory effect as a possible reason for failure to grow *Cl welchii* in attempts to isolate th anaerobe from mixed cultures containing enterococc Guelin, Kreguer, and Le Bris [5] also reported the inhibitory action of a particular enterococcus upon a type-A *Cl welchii* As no other references were traced in a lon search of the available literature, it may be concluded tha the inhibitory effect of some enterococci on *Cl welchii* ha not only received little attention but is not perhaps ver widely known

The effect is not explained by pH change The evidenc is against its being due to hydrogen peroxide, because it i produced under anaerobic conditions on media rich enough in catalase to inactivate relatively large quantitie of hydrogen peroxide Whether or not some property of nascent hydrogen peroxide could bring about this effect might be arguable, but such a hypothesis would no explain the activity of the filtrates or the lack of inhibition of such an oxygen-sensitive organism as *Cl tetani*

This inhibitory effect seems worth a preliminary repor because the consistency of the activity against *Cl welchi* has probably not been appreciated and might possibly be of practical value Apart from the usefulness that such an agent might have in preparation for operations on the large bowel, it might have a place in prevention or treatment of the common clostridial enterotoxæmias of domestic farm animals For this reason it is proposed to study this antibiotic effect further

I am grateful to the Curator of the National Collection for the provision of many of the strains used I am also indebted to Mr George Kerr for the accompanying photograph

Medical Societies

MANCHESTER MEDICAL SOCIETY

AT a meeting of the Section of General Practice on Feb 22 Pitfalls in the Diagnosis and Management of Blood Diseases were discussed by Dr M C G ISRAËLS

Dr Israels said that in the first place it is necessary to establish whether anæmia is present, and this is best done by estimating the hæmoglobin or having a blood-count done It may be impracticable to deal with all patients this way, and it is usually safe to treat females with oral iron for one month and send them for a blood-count if there has been no response Males with anæmia should never be treated without investigations It is most important to use only simple iron preparations, such as ferrous sulphate or gluconate, and never to use compound hæmatinics

When a blood-count is available, the course of action in general practice may often be determined by the colour-index, but all patients with a hæmoglobin level of less than 40% are best sent to hospital without delay for further investigation—particularly patients with anæmia and a polymorph leucocytosis, since this often indicates some malignant factor If the colour-index is less than 1, women under 50 can be treated with oral iron for one month, but males of any age, women over 50, and girls under 16 should be further investigated before treatment When the colour-index is about 1, women again often prove to have simple iron deficiency But there are two other anæmias with this sort of picture anæmia due to renal failure and aleukæmic leukæmia, these can be detected only by full hæmatological studies When the

---

4 Smith, L DS Introduction to the Pathogenic Anaerobes, p 61 Chicago, 1954

Ann Inst Past 1947, 73, 1036

colour-index is over 1 there is a great temptation to diagnose pernicious anæmia and to give treatment without further investigation, but this is a dangerous and bad practice, for there are several other causes of such a blood picture These include acute leukæmia, acquired hæmolytic anæmia, steatorrhœa, and aplastic anæmia The management of these conditions differed widely Consequently such patients should be sent to hospital for investigation and never be given cyanocobalamin (vitamin B$_{12}$) while waiting to be seen, ill patients should be seen within twenty-four hours at any properly organised hospital

Reviews of Books

Metabolic Care of the Surgical Patient

FRANCIS D MOORE, M.D, Moseley professor of surgery, Harvard Medical School, surgeon-in-chief, Peter Bent Brigham Hospital, Boston Philadelphia and London W B Saunders 1959 Pp 1011 140s

IN modern surgical practice the study and care of the metabolic aspects of disease becomes increasingly important No one person has more significantly influenced this alteration in surgical outlook than Dr Francis Moore, who has here set out the accumulated knowledge and wisdom from his many years of study of surgical metabolic problems As he says in an introduction, his purpose is " to provide a general text and guidebook for metabolic care in surgery ", and indeed the book covers in great detail practically every aspect of this vast subject.

Divided into six sections, it starts with a consideration of the normal patient, and the normal metabolic changes after operation and during convalescence The remaining sections deal with changes in blood-volume, body-fluid and electrolyte disturbances, loss of body substance, visceral disease in surgical patients, and fractures, wounds, and burns In these last two sections the emphasis is naturally on the metabolic changes, though general surgical management is also discussed in some detail

In each section the problems are dealt with in the utmost detail and from all possible angles, so that the volume is a storehouse of information To those uninitiated in this type of surgical care the mass of intricate information and argument may at times seem daunting, but the book is not intended as a primer, and those who have already mastered the rudiments of the subject will find in it much of interest and value It is a pity that the style is sometimes obscure, and the length of the text is increased by the author's plan of discussing each subject and then adding a separate chapter on the relevant literature, in which much of the information already imparted is set out again with references

The book is profusely illustrated with metabolic charts showing the various changes described, as well as many diagrams, some simple but many complex, representing various physiological and metabolic processes Thus there are nine diagrams illustrating the circulatory changes in shock, many of them with captions of over half a page in small print. The aim of such illustrations is to drive home some important fact or concept, and it is doubtful whether the more complicated charts serve this purpose. The main text is also illustrated by case-histories in which the development and management of actual metabolic disturbances is very usefully discussed. The book is well produced with a good index and a very full bibliography

It is hard to believe that many surgeons will read all this long book, but at the same time it is even harder to believe that there are any surgeons who will not find much in it to interest and stimulate them. To the expert in this branch of surgical studies the book will be invaluable as a source of information and reference. For the undergraduate reader it is undoubtedly too detailed for standard use, but many, by judicious " dipping ", might well have their minds opened to concepts of surgical thought and care of which they might otherwise be unaware Dr Moore's great work is a very valuable addition to surgical literature

Physiology of the Retina and Visual Pathway

Monographs of the Physiological Society, no 6 G S BRINDLEY, M.A., M.D, fellow of King's College and lecturer in physiology, University of Cambridge. London Edward Arnold 1960 Pp 298 35s

THIS instructive book was obviously written because its author had done a great deal of penetrating thinking and sound experimental work on the topics he discusses It deals with photochemistry, electrical activity in the retina, central visual pathways, subjective experiments, spatial, temporal, and adaptational effects on the threshold, and colour-vision Consequently it cuts into carefully selected parts of a highly intricate subject But for whom was it written? The neurologist will dislike the unexplained substitution of " extinction " for " optical density ", and he will not share the author's apparent amazement that the optic nerve should contain a large proportion of fibres not relaying in the lateral geniculate body The histologist will be surprised that Sjöstrand's criticism of De Robertis' work is not mentioned The photochemist may wonder why absorption spectra (extinction or optical density?) of the same substances are ' not quite the same " for a solution and in situ respectively (p 22) but " extremely similar " on p 23 Yet the reader for whom the book is intended, presumably one already acquainted with more than the third-year or primary F.R.C.S account of visual physiology—in short, an expert—will like it. For some lack of balance in treatment is more than compensated by the original thought which Dr Brindley has bestowed on the material The worker in this subject will also be inspired to do quite a number of new experiments, and will have learnt both how to correlate various results and, if he is wise, how not to do it. In short, he will benefit by reading this book.

Postvaccinial Perivenous Encephalitis

ERNST DE VRIES, emeritus professor of neurology and neuropathology, and neuropathologist, neurological clinic, University of Utrecht, The Netherlands Amsterdam Elsevier Publishing Company London D Van Nostrand. 1960 Pp 181 38s

THE author has made a study of the pathological changes in the brains of most of the cases of postvaccinial encephalitis which have occurred in Holland since 1925 From the 62 cases which he has collected he separates a group of 29, these show a pathological picture described as a perivenous microglial type of encephalitis, with focal demyelination The clinical condition usually arises after vaccination against smallpox—i e., infection with live vaccinia virus—and much more rarely after measles rubella, or varicella, and Professor de Vries considers that a firm diagnosis of this particular variety of encephalitis can be made only after histological examination of the nervous system

The description of the pathological changes is useful, but the illustrations are not always adequate. A moderate amount of space is devoted to clinical descriptions of the cases, and the literature on postvaccinial encephalitis is discussed fairly briefly

The book will interest neurologists and neuropathologists since it presents both clinically and pathologically an interesting series of cases of a rare condition, but it cannot be said to throw much light on the fundamental problems of encephalitis or demyelination

Care of the Dying

CICELY SAUNDERS, M.B. *Nursing Times* Reprint London Macmillan 1959 Pp 32 2s

THE care of the dying and the clinical, emotional, and spiritual aspects of death are passed by in the medical curriculum, and little taught to students or even to housemen in the wards of teaching hospitals It is probably as easy now as it was 40 years ago to go into practice consciously and lamentably ignorant of all these matters and with a strong tendency to leave them to nurses or even to relations Into this little booklet Dr Saunders has poured an astonishing amount of informed instruction, advice, and recorded observation She has been in turn nurse, almoner, and, it seems, medical superintendent of " terminal care " hospitals, and she writes with well-earned authority She early makes it clear that she writes also as an Anglican Christian, believing that " by Man came death ", but any medical reader who quits at this point because he cannot accept this doctrine will lose a great deal of very practical instruction in devices for the relief of pain and distress and the skilful use of drugs The booklet deserves to be very widely read and might well be expanded into something larger

Carcinogenesis of Ultraviolet Light

HAROLD F BLUM, physiologist with the National Cancer Institute, and visiting professor of biology, Princeton University Princeton Princeton University Press London Oxford University Press 1959 Pp 340 52*s*

THIS book explores, in lively and evocative language, the process by which ultraviolet light induces cancer The earlier chapters deal with the various effects of ultraviolet radiation on biological systems, and though they are preparatory to the main part of the work—the construction of a model for this system of cancer formation from quantitation of the (considerable) experimental data—they are very interesting in themselves

In Dr Blum's model, the tumour is shown to grow with regularly repeated dosage, by the proliferation of an increasing number of clones of cells, the proliferation of which is constantly accelerated. This increase in rate of proliferation (which is inherited) is best explained on the basis of quantitative increase in some replicated pattern (carried by nucleic-acid templates or " tems ") within the cells Thus the cancer cell can be held to differ from the normal only in containing a greater number of " tems ", which may accumulate within the cell in a variety of ways The acquisition of " tems " by a cell results in its neoplastic transformation.

The " tem " hypothesis which the author extends to other cancer systems is an extrapolation, and Dr Blum is at pains to distinguish it from the quantitative bedrock of data which showed the process of cancer formation by ultraviolet light as continuous, cumulative, essentially irreversible, and non-threshold As for the latter, it would be exceedingly difficult to derive a more cogent interpretation of the data The speculations arising from the extrapolation seem less convincing in that little or no consideration is given to the specificity of action of carcinogenic agents Taking Dr Blum's hypothesis to its logical conclusion, all that is required is the chronic application of some minimal trauma

British Encyclopædia of Medical Practice (*Cumulative Supplement, 1959 Medical Progress, 1959* London Butterworth 1959 Pp 445 35*s* Pp 325 37*s* 6*d*, combined price 67*s* 6*d*)—The first of these two volumes is essential for those who own the *Encyclopædia* and wish to keep it up to date It consists of additions and emendations to articles already in the *Encyclopædia* and is therefore of interest only to those who have the other volumes *Medical Progress*, though printed and bound uniform with the *Encyclopædia*, can well stand by itself It contains a series of critical surveys of various aspects of medicine and surgery, and includes a special section on therapeutics and new drugs There is also a short section devoted to abstracts of important papers, ranging from acidosis to whooping-cough The *Encyclopædia* is a well-established favourite, and these volumes, produced under the editorship of Lord Cohen of Birkenhead, maintain a high standard The only distinct gap is that there is too little about the problems of old age, and perhaps the 1960 edition might include a survey of developments in geriatrics

New Inventions

A SIMPLE BED CRADLE

AFTER a few days in bed the weight of bedclothes on the feet becomes uncomfortable, predisposes to pressure-sores of the heels, encourages foot-drop, and disturbs tone in the leg muscles (which I suspect makes them weaken quickly)

Bed cradles of semicircular design are unsatisfactory because patients often knock their shins on them, even when they are padded Also they are expensive Other bed cradles tend to take up too much of the bedclothes for comfort, are awkward to manipulate, and are more expensive

A simple bed cradle can be made from an 8-ft length of $^{1}/_{4}$ in mild steel rod The stages are illustrated in fig 1 Apart from welding the two ends together at stage 3 no special skill is required

In most cases one cradle only is needed at the bottom of the bed (fig 2) Other patients require one on either side of the mattress to keep the bedclothes well clear of the limbs (fig 3) Occasionally three cradles—at the bottom and at either side of the mattress—are necessary

Though greeted with little enthusiasm, these bed cradles soon became popular with the nursing staff of the geriatric ward at Shenley Hospital, St Albans They are light to carry, easy to manipulate, and simple to store They can be manufactured as an occupational-therapy project. The cost of the raw materials is about 1*s* 4*d*

Acknowledgments are due to the engineers at Shenley Hospital, who made the prototype, to Miss Shirley Ogden, under whose ægis many more cradles were made in the occupational-therapy department, and to Miss H M Collins, who took the photographs

Expired-air Resuscitation

METHODS of artificial respiration have to be tested by doctors but applied by laymen—a fact which should be borne in mind when their merits are discussed. Expired-air resuscitation has aroused considerable interest in the past few years, and a realistic appraisal of its value is required. Such an appraisal is not easily arranged. Ideally, it calls for the bringing together of a patient with acute respiratory failure and a rescuer without medical training, in the circumstances of real life. (These may include emotion, vacillation, conflicting advice from bystanders, storm and tempest, unsuitable clothing, weeds in the windpipe, and mud in the mouth.) Such circumstances preclude objective measurement. Scientific assessment can be made only in the relative calm of a medical establishment, and must inevitably be unrealistic. No normal volunteer, however cooperative, can imitate the behaviour of a patient with acute respiratory failure. To induce such failure the respiratory muscles must be paralysed by one of the relaxant drugs, and few subjects are so phlegmatic that they will endure this while remaining conscious. Assessment must therefore be made on anæsthetised paralysed subjects (who must be properly looked after) with the help of equipment designed to measure the efficacy of the artificial respiration. Several such studies have, in fact, been undertaken[1-3], and this issue includes the results of a trial by Lieut.-Commander COX, Professor WOOLMER, and Petty Officer THOMAS.

These studies leave no doubt that expired-air artificial respiration, in the circumstances of the investigations, is an effective method, superior in some respects to all others available to laymen. Mechanically the chest can be compared to a bellows, but it lacks the handles by which the sides of the bellows can be drawn apart. This lack accounts for our relative inability to *pull* the chest open—a difficulty which can be effectively countered only by such elaborate devices as the cabinet respirator—and gives the advantage to methods of *pushing* it open by positive pressure applied to the inside. The positive method has the additional merit that a means of producing the required airflow is at hand in the respiratory apparatus of the rescuer—an apparatus well suited to this purpose and with an ample reserve of power. It is not surprising, therefore, that expired-air resuscitation can ventilate the lungs, in ideal conditions, better than any of the manual methods. "Ideal conditions" implies an unobstructed airway in the patient, and a gastight connection between the airways of the patient and the rescuer. An unobstructed airway is of course essential with any method: it can more easily be obtained with expired-air resuscitation because the hands of the operator are free to support the jaw and extend the head. The requirement of a gastight fit is peculiar to the positive method, and difficulty in attaining this is one of its disadvantages.

This difficulty is least if the mouth of the rescuer is applied directly to that of the patient, but the æsthetic objections to this practice are formidable. The interposition of a tube gets over the æsthetic objections but at the price of two other disadvantages: the need for a piece of equipment, and the possibility of misusing it.

By a modification of this method an open airway is assured by tilting the patient's head back as far as it will go, and blowing into his nose.[4,5] This is less objectionable than mouth-to-mouth contact, and avoids the necessity for putting anything into the patient's mouth, and it has been found effective by several independent workers. Moreover, it can be applied with the patient in the semilateral position, from which his head can easily be turned to promote drainage from the pharynx.

The positive method is open to the further objection that it impairs the venous return by increasing the mean intrathoracic pressure.[6] A healthy cardiovascular system can easily overcome this disadvantage, but a seriously anoxic one may not. It is difficult to say how important this effect may prove in practice—and of course manual methods involving compression of the chest are not free from the same objection.

How serious are these disadvantages? Inability to maintain a gastight seal is not a serious drawback. An average-size rescuer can easily deliver a litre of air per breath, and comfortably exceed twelve breaths of this volume per minute, so losses by leakage of the order of 30% can be accepted. The need for a tube to avoid the direct application of the rescuer's mouth to that of the patient is a serious disadvantage so far as the general public is concerned. For organised bodies, such as the Armed Forces, fire brigades, police, beach guards, and mine rescue teams, the disadvantage is slight, for the tube is small and inexpensive.[3,7] The possibility of a properly designed tube injuring the patient is remote. The importance of draining the lungs is often exaggerated, and of course acute respiratory failure is not always the result of immersion or of poisoning by anticholinesterases. If there is a pulmonary circulation, water is quickly absorbed into it from the lungs. If there is not, artificial respiration is probably useless anyway. The possibility that fluid regurgitated from the stomach may be blown into the respiratory tract is more disturbing, but regurgitation is much likelier to result from compression of the trunk, which is a part of the manual method, than from expired-air resuscitation.

What is peculiar to expired-air resuscitation is that it cannot be taught by practice on conscious volunteers, because of æsthetic objections. This does not mean that it cannot be taught at all. On the contrary there is good evidence that it can be taught quite easily. In a

recent study in the U S A all of 87 untrained rescuers were able to insert an airway and produce satisfactory ventilation after one demonstration [8] Teaching films have been made in North America and Denmark, and copies of at least one [9] of them may be had in this country Working models, or mannikins, are being made in the U S A, in Canada, and in Denmark, and can also be obtained here They give a sufficiently life-like impression of the human respiratory tract for demonstration of the method, and of the mechanism of airway obstruction and how to avoid it Nevertheless, the need for such aids may prove an insurmountable obstacle to those who teach respiratory resuscitation as a part of first-aid classes for the general public, for much of this teaching takes place in schools and youth clubs which lack the necessary resources

This method has been adopted by the U S Army and Navy and recommended by the American Red Cross as that of choice when the patient is a child Reports of the use of expired-air resuscitation " in earnest " are still too few to warrant conclusions, and anyhow one can never be sure that a patient who has been resuscitated by one method would not have responded equally well to another The experimental evidence of the efficiency of expired-air resuscitation is, however, so strong that it should be accepted as an alternative to the established methods in most circumstances, and as superior to them in some—for instance, when the patient has chest wounds or when the rescuer must work in a confined space Acute respiratory failure may be a transient disorder, quickly fatal if untreated but often completely reversible without sequelæ by prompt and effective action Doctors and first-aid workers should be prepared

Precancerous Lesions of the Vulva

EVER since the original work of BERKELEY and BONNEY,[10] leucoplakia of the vulva has been regarded as the most important factor in the causation of vulval carcinoma Unfortunately there is disagreement—in particular between gynæcologists and dermatologists—about the precise lesion to which the term " leucoplakia " should properly be applied

To the gynæcologist leucoplakia is a disease which may arise in hypertrophic or in atrophic form, and may affect part or all of the vulva except the vestibule and the urethral orifice, and may even extend laterally to the folds of the thighs and backwards to surround the anus The affected skin has a whitish, sodden, or parchment-like appearance, with cracks and fissures which are largely the result of scratching caused by the intense pruritus In the hypertrophic phase the microscopic appearances are of epithelial overactivity with severe hyperkeratosis and thickening of the epidermis, the rete pegs dipping downwards in a pointed form into the dermis, which shows absence of elastic tissue, hyaline degeneration of the collagen, and round-cell infiltration, it is in this stage that the risk of malignancy is thought to be greatest The disease may later pass into an atrophic form with similar dermal changes, but with atrophy of the epidermis and flattening or disappearance of the rete pegs, although considerable hyperkeratosis remains, the precise relation between this atrophic phase and the development of carcinoma is seldom clear In the view of BERKELEY and BONNEY [10] the disease at this stage is quiescent, pruritus has ceased, and the patient does not complain TAUSSIG,[11] however, doubted whether a final phase of complete inactivity exists, and certainly intense pruritus commonly persists when the skin shows this atrophic appearance

The dermatologist's view [12] [13] is somewhat different The condition described by gynæcologists as the atrophic phase of leucoplakia they term lichen sclerosus because of the great similarity, both macroscopically and microscopically, between the vulval lesion and other lesions of lichen sclerosus, which may be found elsewhere on the body The term leucoplakia they confine to whitish patches similar to those of lichen sclerosus, but with more induration, which are limited sharply to the vulval area and do not extend beyond the outer margin of the labia majora or into the perianal region The microscopic appearance is that of the hypertrophic phase already described

If we accept this view, which seems to have more to commend it, and if we employ this terminology, are we to regard the chronic whitish irritating vulval lesion as precancerous? In a group of cases with vulval soreness or pruritus, WALLACE and WHIMSTER [12] found 20 patients with lichen sclerosus, in all but 2 of whom perianal skin was also involved, and in 6 of whom lesions were present elsewhere, notably on the trunk and breasts, careful follow-up of these cases with frequent biopsy showed the changes of leucoplakia in 5, in 2 of whom the lesion subsequently progressed to carcinoma —in short, the gynæcological order was reversed In the same series WALLACE and WHIMSTER found that leucoplakia was not necessarily preceded by lichen sclerosus, for in 5 cases the leucoplakia was superimposed on severe atrophic change (described as primary vulval atrophy), while in 21 cases of leucoplakia no other vulval disease was found Similar findings are reported by STENING and ELLIOTT [14] Examination of a group of patients with chronic vulval lesions, but without obvious cancer, showed the changes of lichen sclerosus alone, the changes of leucoplakia alone, or both groups of changes together in three-quarters of the cases remaining after other obvious lesions had been excluded In both series the microscopic appearances of leucoplakia were not found outside the lateral margin of the labia majora, in the perianal region, or in the folds of the groin In STENING and ELLIOTT's series, of 52 patients with carcinoma of the vulva nearly two-thirds were found to have pre-existing leucoplakia, while in only a fifth had the carcinoma not been preceded by other disease

Since leucoplakia may arise de novo or be preceded by such chronic lesions as vulval atrophy or lichen sclerosus, and since lichen sclerosus at least is not precancerous in other situations, even as near as the perianal region, the main factor in vulval carcinoma is perhaps the liability of the sexual skin to undergo malignant change JEFFCOATE[15] believes that any chronic skin disease or irritation of the vulva may lead to carcinoma in a susceptible woman In any one case, only biopsy will show whether epithelial overactivity exists, so in any patient with pruritus and a suspicious lesion biopsy specimens from several sites on the vulva should be obtained If the changes are found to be those of lichen sclerosus and the patient can be kept under careful observation for a considerable time, further surgical treatment, except biopsies, may not be required The appearance of leucoplakic changes, however, is an indication for local vulvectomy If the leucoplakia has arisen de novo the patient may be cured, if it is superimposed on lichen sclerosus the removal of the skin with the special precancerous tendency has been achieved, even if other areas of lichen sclerosus in the perineum or on the nearby skin give trouble later

Epidemiology of Influenza

INFLUENZA is the rogue among epidemic diseases, suddenly cutting loose and sweeping across the world with a speed and a ferocity unequalled by any other disease The great advances in our acquaintance with the causal viruses since the first was discovered by SMITH, ANDREWES, and LAIDLAW[16] in 1933 have not been paralleled by an equivalent understanding of the epidemiology

The mechanism of an epidemic of measles or smallpox is now well understood, but epidemics of influenza cannot yet be interpreted by applying the same methods WATSON[17] has taken these difficulties as the starting-point of an unusual and detailed research among 176 families in his rural general practice The occurrence of Asian influenza in late 1957 presented the opportunity to observe the progress of the epidemic until it died out in the third and fourth months of 1958 HOPE-SIMPSON and SUTHERLAND,[18] studying the 1951 epidemic of virus-A influenza, had been unable to show unequivocally that the virus spread within the household or to determine a regular serial interval, which is a measure of the host-parasite cycle WATSON presents evidence that the Asian virus was in fact spreading within the household, that inapparent infections were occurring, and that house contacts of persons known to be infected with the Asian virus did escape the infection He considers that his evidence points to a constant incubation period, most commonly of two days, and to a serial interval varying from one to ten days but usually of three days He describes other evidence suggesting that the most infectious time is that of the temperature peak, and that the virus is spread by coughing Many of WATSON's patients had a diphasic (M-type) temperature chart and he suggests that the second rise of temperature is due to reinfection of the patient's own respiratory tract by the virus released during the first bout of fever, the incubation period of the second rise being again two days as in the primary attack caught from another person These patients probably had two periods of infectiousness, one each time the temperature rose to a peak

WATSON's own blood, tested at fortnightly intervals, showed no response for the first six weeks during which he was in constant attendance on cases of influenza Subsequently, a rise of complement-fixing antibody against influenza-virus A followed closely on the occurrence of cases of influenza in his family although he himself did not fall ill The blood of his assistant showed a similar picture, although no influenza occurred in his household either before or after his symptomless rise in antibody titre

Even the most attentive and knowledgeable general practitioner cannot eliminate the possibility of paths of infection by which his patients may, unknown to him, have received doses of the virus WATSON's work is a remarkable piece of research of a type for which the general practitioner has an almost unique opportunity but can seldom find the necessary equipment of persistence, enthusiasm, keen observation, and an inquiring and closely reasoning mind

The Asian influenza epidemic is described from a different viewpoint by the Ministry of Health,[19] which has brought together information from general practice, hospital practice, public-health departments, insurance offices, schools, colleges, camps, and laboratories The observation of the Asian epidemic from the time of its first announcement in China has brought us surprisingly little which was not either known or suspected before

Annotations

DIAGNOSIS AND PROGNOSIS

THE changes in the organisation of training which the General Nursing Council are making over the next few years (see p 761) include the reintroduction for parts of the nurses' register of a test of the entrant's educational assets Those who cannot claim exemption on their record in the G C E will be given a test, designed by the National Institute of Industrial Psychology, which is already used in many training-schools on a voluntary basis In making a test compulsory for all training-schools and all candidates, the Council, by excluding the unsuitable, hope to reduce the number of students who fail to complete their course A different entrance test with a different purpose has been proposed by Dr L R C Haward[20] For a predictive test that excludes the girl whose educational standard is inadequate, he would substitute a diagnostic test which discloses her weaknesses, so that during her training she may be given special help and support in making good scholarly or emotional deficiencies In the present shortage of nurses it is important to make the best use of every potential recruit, and in his view an entrance test should ask not " How can this applicant be expected to fare in her professional examination and subsequent career ? ", but " What steps are necessary to make this applicant into a suitable nurse ? " For this purpose he would rely largely on a test of reading ability, such as the one he has described in our columns,[21] which assesses the candidate's grasp of what she has read He chooses this form of test because reading ability has been found to be correlated with personality maladjustments, and because in a pilot study student nurses said that their greatest difficulty was in learning complex subjects from textbooks

The purpose of his test would not be the exclusion of the student but the guidance of her teacher, and with greater reliance on new reading methods, such as visual aids and filmstrips and new textbooks with strip-cartoons, he believes that the less accomplished reader could be helped to succeed She should be allowed to go at her own pace, which might mean a protracted course, and would probably profit from a good deal of individual tuition He is hopeful that even the undesirable trends of personality, which the reading test may have disclosed, could be overcome in the " malleable stage of late adolescence " by the support of tutors and others

The growing complexity of medicine has imposed new responsibilities and duties on the nurse Nursing is said to be the job with the highest level of technical and personal accomplishment which is open to the school-leaver today But alongside the science of nursing the craft of nursing persists, and continued diversification of the nurse's work may in the future lead to the division of the profession into " university-trained technicians or bedside attendants " as Dr Haward puts it The novel possibilities of specialisation of this kind are shown by Mr Hedley Atkins'[22] suggestion that operating-theatres, like physiotherapy or radiology departments, should be staffed by technicians without a general training in nursing

In putting forward their new regulations the General Nursing Council express the hope that girls who are found to be unsuitable for the course for State registration will find satisfaction in rewarding and worth-while work at the bedside The Council recognise that some may be discouraged by the unfortunate title of " assistant nurse " and a rate of pay which is less than that of an untrained nursing auxiliary If the conditions of service were adjusted, some of Mr Haward's " slow readers " might well find their place in this group of nurses Work at the bedside does not necessarily require an I Q of 110, the standard at present set by some training-schools, and it offers scope for other qualities which to the patient seem perhaps equally important Some years ago[23] we suggested that a common basic course might be the first part of the training of all nurses Once qualified in this way, some would want to continue their studies for further higher and specialist qualification, but all would carry the honourable title of nurse On the whole this proposal has not been enthusiastically accepted by the nursing profession and, like all changes, it would no doubt bring practical difficulties But some form of it might be reconsidered, for, if the number of what are at present called " assistant nurses " is to be raised, some substantial changes will have to be made in their status and rewards In the world of today there is no lack of competition for the services of competent, practical, and kindly women, whatever their reading ability, and often these are the very people who will serve the patient best at the bedside

SEROLOGICAL DIAGNOSIS OF SYPHILIS

ALTHOUGH the incidence of early syphilis has fallen steeply since the post-war peak of 1946, there has been renewed interest in the serological diagnosis of the disease The identification of a phosphatidic acid—cardiolipin—as the active principle of the crude-heart-extract antigens used in complement-fixation and flocculation tests has proved an important advance Although cardiolipin itself is serologically inactive, its mixture in definite proportions with lecithin and cholesterol forms an effective antigen which has been used in many standard tests The use of components that chemically are fairly pure has aided the standardisation of reactivity of antigens, and lecithin has been shown to play an important part in determining their specificity

Cardiolipin-like substances are widely distributed in Nature and can be isolated from sources as different as heart-muscle and wheat-germ Reactions between syphilitic sera and cardiolipin, or the older lipoidal antigens, are not specific in the immunological sense, and serologists have always aimed to use treponemes themselves as antigens This aim is realised in the treponemal immobilisation test, which is based on the observation that syphilitic sera contain an antibody which will immobilise and kill treponemes in the presence of complement This test is now generally accepted as a sensitive and specific indicator of treponemal infection, but its technical difficulties have restricted its use to specialised laboratories In the search for simpler alternatives, techniques involving agglutination, immune adherence, and complement fixation with treponemal extracts have been devised, but none of these has yet proved superior to the immobilisation test An application of the fluorescent-antibody technique has been described, and the preliminary results are encouraging [1,2] Treponemes dried on a slide are exposed to the patient's serum, and the fixation of antibody is shown by treatment with an anti-human-globulin serum conjugated with fluorescein Examined by dark-ground illumination with ultraviolet light, the treponemes which have fixed antibody show an apple-green fluorescence

In all these methods the virulent Nichols strain of *Treponema pallidum* is used as antigen As the central problem of culture in vitro remains unsolved, the organisms have to be extracted from infected rabbit testes, so the amount of material is restricted This has led to re-examination of the cultivable Reiter treponeme as a source of antigen This organism has been shown to contain two lipoid fractions (one of which reacts with the reagin antibody in syphilitic sera detected by heart-extract and cardiolipin antigens), a carbohydrate, and a protein This last fraction, which is relatively easy and inexpensive to make, is used in the Reiter protein complement-fixation test, which appears to be a very useful ancillary to routine tests The demonstration that the Reiter treponeme and virulent *T pallidum* share a common group antigen probably explains the high specificity that has been claimed for this new antigen

At present the serology of syphilis is in a stage of transition, and the clinician may be pardoned for feeling confused by the variety of antibodies which his serological colleagues are finding in syphilitic sera Electrophoretic studies of the reagin antibody reacting with cardiolipin and crude-heart-extract antigens have shown it to be a mixture, and different " reagins " may, it seems, appear at different stages of syphilitic infection, reagin is also distinct from the specific immobilising antibody Two agglutinins for virulent treponemes have been found, one of which can be absorbed by lipoidal antigens The antibody-fixing complement with the Reiter protein antigen again differs both from reagin and the immobilising antibody Although the behaviour of these last two antibodies in syphilitic infection is now well documented, such detailed information about the newer tests is largely lacking, and we do not yet know whether any of them will indicate the presence of continuing active infection in a treated patient

The introduction of the more specific treponemal tests has drawn fresh attention to the non-specific reactions given by lipoidal antigens Positive antenatal serum tests may present the clinician with a difficult decision about treatment, and a recent survey [3] suggests that a considerable proportion of the positive findings in pregnancy may be non-specific In these cases the more specific treponemal tests may give valuable help Some disorders of the collagen group, particularly lupus erythematosus, are often associated with persistent non-specific reactions, which are sometimes of high titre These may antedate the other manifestations of the systemic disease, and the finding of a chronic biological false-positive reaction should not be passed over lightly It seems likely that with the diminishing incidence of syphilis non-specific reactions may become proportionally commoner, and it is fortunate that we now have more specific tests to aid in their identification

REST IN BED

WARD sisters delight to see their patients neatly ranged in bed, blankets tucked tightly across their legs, pillows all turned one way, and bed wheels in line Doctors, however, have come to regard lying in bed as a hazardous occupation, for venous thrombosis and pulmonary embolism, retention of urine, bronchopneumonia, joint deformities, and osteoporosis may result

Bed rest is traditional and reasonable in many diseases but of proved value in few Progressive cardiac enlargement and death after rheumatic fever are commoner in patients who have not rested at the onset [4] After myocardial infarction the risk of cardiac rupture is greatly enhanced in restless psychotic patients [5] (and in dogs cardiac aneurysm develops more often after experimental infarction if full activity is allowed [6]) Paralysis is less common in those who have rested in the early stages of poliomyelitis [7] Of all medical treatments of peptic ulcer, only bed rest and stopping smoking seem to increase the rate of ulcer healing [8] Bed rest is usually thought to be the most effective available measure against infective hepatitis [9] (though American soldiers in Korea, managed on more liberal lines, showed no ill effects [10]) And here or hereabouts the evidence ends Beyond this the case for bed rest is based on clinical impression

Burch and Walsh,[11] in New Orleans, have reported good results from long-continued bed rest in 5 young adults with cardiac enlargement and failure of unknown cause Standard treatments for up to two years had been ineffective The patients were strictly confined to bed for up to thirteen months, in cool air-conditioned wards Digitalis and diuretics were continued All showed striking reduction in heart size and clearing of failure

Possibly fashions have changed too much, and some doctors and patients should be less impatient to be moving

ARTIFICIAL LOWER LIMB

AMPUTATION was originally performed to save life, but the indications have been extended and surgeons nowadays may recommend amputation in order to improve function Limbs whose function has been impaired by severe infection, ischæmia, or trauma, or congenitally deformed limbs, may be amputated in the interest of locomotion Obviously the decision whether to advise amputation for such patients depends on the quality of artificial limbs In general, the quality of artificial limbs for below-knee amputations is excellent, and with a below-knee amputation many amputees can lead a virtually normal life but most surgeons would admit that function with an above-knee amputation is much less good Above-knee amputees adopt one of two basic types of gait They may walk with a stiff knee, lifting their pelvis high on the affected side and rolling the leg out with a circumduction movement—the so-called pylon gait This is an ugly gait and requires considerable excess expenditure of energy with much strain on the hip muscles Alternatively, they may walk with a free swinging knee-joint and a resultant abnormal heel rise, again lifting the pelvis on the affected side This gait, too, demands a considerable excess expenditure of energy, and experience has shown that this may significantly shorten life by straining the cardiovascular system of the elderly

At the University of California workers have for some years conducted fundamental research into normal and pathological gait, including the gait of patients with stiff knees and amputees [12] In a normal gait the knee flexes early in the swing phase of walk and then straightens as the heel comes to the ground, flexes slightly in the middle of the stance phase, and again straightens just before the end of the stance phase, and as the foot again leaves the ground flexion begins again. In these movements the centre of gravity shifts little, and the leg acts as a double pendulum thus diminishing strain on the hip muscles and requiring less energy expenditure Energy is absorbed at the knee in order to decelerate the leg and foot during the swing phase, and some of the energy is stored and returned to the system in a later part of the swing phase by continued forward acceleration of the body at a time when most of the body's potential energy is being lost Locomotion is due not only to the push of the swinging leg, but also to the pull of the deceleration of the swinging leg

In the past few years Prof C E L Allen, of Cape Town,[13] and his associates have been working on an improved artificial limb for above-knee amputees which will permit some of these desirable physiological features This limb has an artificial tendo achillis between the heel and the back of the lower end of the thigh-piece of the leg, as a result dorsiflexion of the foot causes slight flexion of the knee, so that at the end of the stance phase of locomotion, when the foot is dorsiflexed, the knee starts flexing before the leg is lifted from the ground In addition, an ingenious spring bias system is incorporated which has three functions (1) it acts as a shock absorber, (2) it prevents over-flexion of the flexed knee on weightbearing during the stance phase (in other words the knee is stable without being either hyperextended or locked by pressure of the heel on the ground), and (3) the spring stores energy during the stance phase and this energy is released on the swing phase to produce extension of the knee, which is slow in the early part of the swing phase but more rapid in the latter part This limb has been found to produce a far more physiological gait than any other limb for above-knee amputees, and æsthetically it has proved more acceptable as the shin-piece consists of a light metal tube covered with foam-rubber and plastic material

An ideal artificial limb should, like a woman's shoe, be cheap, durable, beautiful, and functional It is too early to say yet whether this one will fulfil all these requirements, and it should be tested more widely—in particular full studies of gait and oxygen consumption are essential Professor Allen insists that this type of research should be performed at universities or comparable institutions He has patented the limb with the intention that it shall be available at the lowest possible cost to all persons Whether or not this limb proves widely acceptable, we can all join in wishing the University of Cape Town every success in the endeavour to provide an ideal artificial limb for all who need it

RELIEF OF SPASTICITY

In patients with spastic paraplegia, whether the lesion of the spinal cord is complete or incomplete, reflex spasm of the lower limbs often causes severe disability Usually these spasms follow any slight stimulus to the legs, and often they seem to occur spontaneously, and they give rise to flexion at the hips and knees, and less commonly to extensor spasms These episodes are painful and exhausting for the patient, and they cause serious difficulties in nursing While in many cases if the spasms can be abolished the remaining voluntary power is inadequate to give useful movement of the limbs, in others the spasms are entirely responsible for inability to walk, and their abolition will allow a much wider range of activity It is therefore not surprising that many methods should have been tested in attempts to overcome these disabling reflex movements Pharmacological, surgical, and physical methods have all been tried

The many drugs which have been employed include barbiturates, mephenesin, curare, chlorpromazine, zoxazolamine, methocarbamol, meprobamate, and thiocolchicoside Each of these drugs has brought about relief in isolated cases, but none has proved consistently effective, and often the dosage required to produce benefit has resulted in unpleasant side-effects From Australia O'Rourke et al [1] now describe the use of tigloidine, which may prove to be the most effective oral remedy yet employed for this purpose Tigloidine is a close homologue of atropine, but in therapeutic doses it produces no parasympatholytic side-effects, nor apparently does it depress respiration or cause muscular paralysis in daily doses of up to 30 mg per kg body-weight Many patients were treated with up to 2000 mg daily without significant side-effects except elevation of mood Altogether 21 patients were treated, all had spastic paraplegia with muscular spasms Only 1 patient failed to derive any benefit, the remaining 20 showed considerable relief of muscular spasms and spasticity If these results are confirmed tigloidine is likely to be a useful drug in the treatment of such cases

Surgical methods have also been of value in certain cases Anterior rhizotomy, section of peripheral nerves, and repeated procaine injections of, say, the sciatic nerve are all successful occasionally [2] but have the serious disadvantage of paralysing completely the muscles supplied by the motor roots or nerves concerned Hence these techniques are not usually applicable to ambulant patients Similar unwanted effects follow intrathecal injections of alcohol [3] and mephenesin,[4] and these drugs also affect sphincter control adversely More recently it has become apparent that intrathecal injection of phenol in 'Myodil' or in glycerin may be singularly effective in relieving flexor spasms [5] [6] without producing unpleasant permanent side-effects In two important communications Nathan [5] and Kelly and Gautier-Smith [6] have described in detail the technique of giving the injection and the results in two substantial series (Intrathecal phenol in lipid solution was first employed by Maher [7] for the relief of intractable pain, and he was also the first to record [8] the relief of flexor spasms by intrathecal phenol) As Nathan points out, the injection in effect produces a chemical anterior rhizotomy, but the loss of voluntary power, though generally sufficient to abolish or greatly reduce the flexor spasms, is seldom complete The solution most often used is 20% phenol in glycerin, and the amount injected at one time is 0 5–1 5 ml, according to the number of roots to be attacked The patient is carefully positioned so that the injected material will flow downwards on to the roots concerned, and this position is maintained for some thirty minutes Some days or weeks later the injection can be repeated in order to affect the contralateral roots Nathan has treated 25 patients, and Kelly and Gautier-Smith 32 patients Cases of cord injury, disseminated sclerosis, motor-neurone disease, and many other conditions were included Relief of symptoms was achieved in all, and sometimes this was dramatic Some patients who had not walked for several years were enabled to do so, and in the others the relief of spasms made nursing very much easier Disturbance of bladder control commonly follows the injection, and is occasionally permanent, particularly after bilateral injections, but in many cases this complication can be avoided, and with improved techniques it may even become avoidable in all There can be no doubt that judicious intrathecal injection of phenol has transformed the lives of many patients with severe flexor spasms In view, however, of the Australian work referred to here, it would seem justifiable to recommend a preliminary trial of tigloidine, which alone may suffice to relieve symptoms in some of the less severely affected

THE PERSONAL DOCTOR
AND HIS RELATION TO THE HOSPITAL

Observations and Reflections on Some American Experiments in General Practice by Groups

T F Fox
M D Cantab , LL D Glasg , F R.C P

IN this country we have one big experiment in medical care, and a few little ones In the United States they have a great many experiments, and I went to see some that bear on the future of general practice

What I shall describe is not the pattern of American medicine but rather the efforts of people who are trying to improve on that pattern And obviously my few weeks in the States do not entitle me to say whether, or how far, any of these efforts will succeed But of one thing I am certain—that an occasional look at what is being attempted in other countries can help us to decide what we really want for ourselves Or don't want

* * *

Some forty years ago the Soviet planners, for their part, decided that general practice was already an anachronism even first-line medical care, they said, should be given by specialists Hence in the Russian town the patient goes to a policlinic, and in the country he goes to a small hospital staffed by a team consisting perhaps of a surgeon, an internist, a pædiatrician, and an obstetrician In Russia the equivalent of our general practice is thus provided by low-grade specialists, who are the peripheral and most subordinate officers of a unified medical service

In Britain since 1948 we have taken quite a different line we have declared that hospital work is for specialists but general practice is (and ever shall be) for general practitioners Our practitioner is and remains an independent doctor, whose professional prestige can be as high as that of his hospital colleague The previously growing tendency for practitioners to become part-time specialists has been checked by putting the two branches of medicine under separate management Thus general practice as we know it has been preserved for posterity—carefully sheltered from the prevailing wind of specialisation

In America, where this wind has sometimes been a hurricane, one can study its effects, and they include some alternative ways of doing the work that general practitioners do here When I have said something about these, I shall return to the question I took across the Atlantic Is the independent practitioner really out of date? Would his functions in fact be better performed by medical groups based on the hospital? If we continue to preserve him, what exactly are we trying to preserve?

PRACTITIONERS WITH BEDS

General practice in Britain and America differ strikingly, of course, in their relation to the hospital

In Britain, as I have said, the tendency before 1948 was for practitioners to develop a specialty, and quite a lot of them combined family doctoring with surgery Unfortunately, in cottage hospitals with small staffs, some of these did far more difficult surgery than was proper and reaction from this abuse was probably the main reason why, in the new service, the hospital boards deprived so many practitioners of the beds they formerly controlled The public, it was felt, would be safer if nearly all specialised work were put in the hands of whole-time specialists rigorously selected for the purpose, and the large majority of the 23,000 N H S practitioners cannot now look after their patients in hospital In England and Wales fewer than 10,000 beds remain in their large

In the United States, by contrast, the majority have easy access to hospital beds Most of the community hospitals (which correspond to our former cottage hospitals and other voluntary hospitals) were originally built on the plea of the local doctors, and the classical pattern is that all these doctors are on the staff What surprised me, however, was to find that the staffs of even large and important hospitals often include people who, if not general practitioners in the more comprehensive sense, are undertaking general medical care Accustomed to the sharp British division between Specialists and Others, I expressed this astonishment

> "This may be fine for the doctors," I said "but if I get as far as a big hospital, I want to be treated by someone who's giving his whole time to hospital medicine Maybe you don't let a general practitioner operate, but, even so, some medical emergencies are just as tricky as surgical ones For my full-time illness, I want a full-time specialist, not a part-time one, even if he *has* been looking after my health for years "

But the Americans, naturally, have an answer to this, and a good one It is that the large American hospital, like the American home, has fewer *doors*—that life inside it is lived more publicly

INTERNS AND TEACHERS

Dr A, a youngish internist,[1] is still only a part-time specialist in that he does what we should call general practice at a health centre, visiting patients' homes, but he is also one of the 200 doctors on the staff of the local community hospital and is on the teaching staff of a famous hospital in Boston "When I send a patient in," he told me, "the intern gets busy, and then the resident, and treatment is started The intern may ring up to say what he's doing By the time I visit, all the wheels may be in motion " Though this patient is Dr A's responsibility, the whole-time staff will do teaching rounds on his cases, and so may members of the visiting staff—a distinguished hæmatologist, for instance, on an occasional pastoral visit

In a big teaching hospital the chief of the medical service may actually think of his department as a hierarchy in which he has final responsibility for all patients, though he delegates it to some part-timers In smaller hospitals, no doubt, a full-time chief will be more anxious not to seem to interfere with the treatment of cases admitted under their own doctor. But, even so, Dr A thought it the duty of any chief of service to interfere if a mistake comes to his notice. The other day, for instance, his chief of service had tactfully rung him up to ask whether he knew that one of his patients had lately been on cortisone, which might be an alternative explanation of some of her symptoms. "No offence intended," said Dr A, "and none taken."

---

[1] Internists are specialists in internal medicine—i e, general physicians Interns are junior housemen, and residents are senior housemen

The key to all this is the word *teaching*. At first, in my insular way, I interpreted this as instruction of students, but the Americans very rightly apply the word also to instruction of interns and residents, which means that any round with junior staff, in any hospital, should be a teaching round (though I gathered that it all too often is not). The full-timer who can take his juniors to see and discuss any case in the hospital, in even the most private bed, can be a pretty effective safeguard for the patient against errors arising from insufficient knowledge or attention, and the publicity of practice in a large hospital means that the doctor who admits the patient, though he retains responsibility, will readily get advice if need be, even if he does not seek it.

Admittedly, a great many American hospitals—even quite big ones—have no interns and no full-time specialists: they are staffed entirely by people who are doing general practice as well as hospital work. But the number of such hospitals is likely to diminish. The trend towards specialisation is manifest in efforts to persuade the hospital authorities to appoint a full specialist as chief of each main service—or at the very least a surgeon who does nothing else but surgery. The hospital may then rule that at all operations the full-time surgeon shall be scrubbed up and ready to help, or a plan may be introduced whereby the surgeon assists the practitioner with the easy operations while the practitioner assists the surgeon with the difficult ones.

COLLECTIVE RESPONSIBILITY

The lack of fully specialised staff means that at present one's chances of dying quietly in a hospital bed with the wrong diagnosis are higher in America than in Britain.—Quietly in the sense that nobody knows, except perhaps the nurses, or that if one's colleagues know, they can do nothing about it.

But here again the risks of a libertarian system are being countered by characteristically American devices. Already two years ago some 75% of general hospitals (though only 25% of hospitals with less than fifty beds) were approved by the Joint Commission on Accreditation, which means not only that they reach a tolerable level of facilities for patients and staff but also that the doctors take steps towards collective responsibility for their work. Thus, on the surgical side, records must include a provisional diagnosis, recorded wherever possible before operation; all tissues excised must be reported on by a pathologist, and a "tissue committee" must report periodically on these data. Likewise admissions and discharges (including deaths) may be discussed at one of the monthly meetings, which must be attended by at least half the staff. Some hospitals hold "case conferences" at which one or two doctors are asked to discuss a subject in the light of their (not always very good) results. A neighbouring medical school, invited to provide lecturers, may send one or two senior men to look through the hospital records, in search of subjects on which teaching is specially desirable. And sometimes an attempt is made to assess the quality of the hospital's work by a formal review—a "medical audit"—of its records and the activities of its doctors.

An experienced medical administrator said to me that in a good hospital such formalities as tissue committees and medical audits do more harm than good: what really matters is to have a staff that trust each other and consult each other fully. But they can be, and are, a great help to the reformer who—sometimes against heavy odds—is bent on raising the standards of his hospital. I was assured, moreover, that American doctors generally do not mind their failures being discussed by colleagues—even colleagues with whom they are competing for practice—provided the discussion is private. Like the Russians and the Chinese, they claim to be able to tolerate sessions for self-examination—a moral accomplishment which we British so far show little sign of emulating.

FREEDOM—WITH SAFEGUARDS

But I must not wander too far from my argument. The main point I have made so far is that, whereas in Britain all but a few hospital beds are reserved for full specialists, in the United States a great many such beds are at the disposal of general practitioners and part-time specialists. Hence the profession is not, as in England, sharply divided, at the hospital gate, into specialist sheep and generalist goats.

This American system can work well—for the patient as well as for the doctor—provided the hospital's standards are set, and unobtrusively preserved and promulgated, by full specialists. In the large hospitals these men exert their influence through consulting with the part-time staff and through teaching the interns. In small ones the patient gets increasing protection (though sometimes posthumously) from critical reviews by outsiders and by the staff themselves.

VARIOUS KINDS OF GROUP

In America, as in Britain, a great many practitioners are still in "solo" practice. I met a few of them, including one so oldfashioned as to prefer to practise from his own home ("far more convenient than driving down to an office every time a patient calls"). But I am less concerned here with the ways in which American practice resembles our own than with some of the innovations—the efforts to do something different. My picture is correspondingly distorted, and the reader (like the visitor to the U.S.A.) must everywhere remember that "this, of course, is not America."

What I was looking at were various forms of group providing first-line medicine, and in its simplest form such a group is the same as an English partnership, except that its office will be equipped for more investigation and may have more ancillary staff—besides being probably a better building with more amenities. Among the people I would gladly have as my family doctor were two partners in a small town in Wisconsin (one of whom, as a university preceptor, always had a student under instruction) and three men working from their own centre in North Carolina but also teaching on outpatients in the university hospital.

Where the American groups diverge from their British counterparts is when they begin to turn into clinics offering *specialised* investigation and care. Sometimes the result is a modest affair proportionate to local needs, but sometimes it is—well, the Mayo Clinic. The process begins through the drive of some doctor who sees that the requirements of the neighbourhood are not being met, or one who must have a larger supporting structure for his genius, or one who merely wants to expand his business or find scope for his organising talent. But as the group gets going it may develop a life of its own, and new motives. I was fortunate enough to see what seemed to be various stages of this process, as well as several different types.

Natural History of the Private Clinic

The first two were still at the stage of being expressions of a personality.

1. *An Organised Partnership*

One was in a little mountain town. On the best available site within easy reach of the hospital, a well-qualified surgeon was practising with two associates. His long shed-like building was unpretentious, but as an artist he had lined each room with a different wood, and had given the consulting-rooms the friendly look of home. As an organiser, however, he had pursued Modern Efficiency as far as she would go (which is sometimes rather further than she ought), with light signals outside the examining-rooms, internal loud-speaking telephones by which anybody could talk to anybody, and music from the consulting-room ceiling. My guess is that this little mountain practice will soon get bigger and more specialised.

2. *An Enlarging Clinic*

The other had already done so.

Before the war three doctors, with local support, transformed an old school into a small hospital. This they then transferred to the community, but a symbiotic arrangement was made whereby the hospital took part of the private doctors' fees and in return provided them with “ offices, nurses, technical staff, equipment, laboratories, medicines, bookkeeping services, and other conveniences ”.

A condition of the public grants with which the hospital is being rebuilt to 100 beds is that the private clinic shall no longer be in the same building, but hospital and clinic will continue to be “ mutually convenient to each other ”. Under the leadership of an able and indefatigable surgeon, aided by an able administrator, the clinic and hospital represent a big addition to the medical resources of the area, but it still seemed to me more of a private enterprise than a public utility.

The doctors in the clinic all work for their own fees: the surgeon thinks that salaries lead to laziness and slow work. Some of them still provide general medical care from their clinic offices, and I asked one of these whether he really *liked* listening to patients with minor ailments. With a wry smile he replied: “ It's worth it.”

SECOND GENERATION

The two groups I next describe belong to the second generation, having proved viable after their originator had gone. The first is interesting because, though it is a specialist group, general practice in the neighbourhood is still an important part of its activities. The second illustrates the natural fate of general medical care in an increasingly specialised organisation—unless a deliberate effort is made to preserve, develop, or transform it.

3. *A Clinic with Much General Practice*

A quarter of a century ago a doctor working from an A.D. 1750 mansion in a township near Boston decided to give up his lawn and build a medical centre. Much enlarged, this is now owned and run democratically by the Dedham Medical Associates. Specialists of all the main kinds have sessions at the clinic, and both consultations and investigations are easily arranged. But, as I said, the really noteworthy thing is that this medically sophisticated group is still providing personal or family medical care for the local community (as its founder did in his nextdoor mansion), and, stranger still, the five members of the group who do this are paid individual fees and are thus in competition not only with the local practitioners but with each other.

These five doctors are not general practitioners but internists, and they can take their patients into the hospitals where they are on the staff. Normally they see their patients at the clinic, where each has his own room, but they pay home visits, up to 20 miles away—the fee being perhaps 5–7 dollars for an ordinary home visit, mounting to as much as 25 for a long distance. Even though the clinic is now long established, local practitioners never refer cases to it, but neither external competition nor internal competition seems to disturb the group's equanimity. Patients sometimes want to change their doctor, but (said the present chairman) if one joins a group one must be prepared to give and take: what matters is not what is good for the doctor but what is good for the patient. New members are chosen with deliberation, and during the first year they spend some five months deputising for their seniors when these are on holiday. At night the telephone is answered by a lay person who is paid to take and refer the calls: at weekends *three* of the five doctors are on duty, for it is found that if the weekend work is done by only one he is exhausted on Monday.

4. *A Clinic with Little General Practice*

From this relatively small building in a populous area we pass to a remarkably big one in the little Wisconsin town of Marshfield, which has perhaps 10,000 inhabitants. Like the Mayo Clinic in neighbouring Minnesota, the Marshfield Clinic exports medical care, getting patients not only from its own State but also from far away, and that is the reason why the Roman Catholic sisterhood who provide the 280 pay-beds at the local hospital are already finding these too few. Several of the clinic staff of 38 specialists have appointments in universities, and at least one has an international reputation, but for old time's sake the internists among them still accept local people as their personal patients whom they visit if need be.

For all this arose out of a general practice. The founder, Karl W. Doege, “ only a small town doctor but full of love for his profession ”, believed in better diagnosis and treatment through “ intimate association of physicians in their work, constant study and mutual assistance ”,[2] and in 1916 he brought five other men into a well-knit clinic group.

The members of this group, joining after three years' probation, are paid on the same scale regardless of specialty or number of patients seen: “ our present plan is based on the assumption that each physician is as valuable to the organization as any other ”. Related to age, experience, and years of service with the clinic, salaries rise till 60 and then decline till 65, when the member loses his vote.

Providing security and fine facilities for work, the clinic is virtually (though not legally) a non-profit-making organisation. People who regard it (or one of the members) as their own doctor pay lower fees than the far larger number who are referred for consultation, and sometimes a little embarrassment arises over referrals because the clinic is thus in competition with the other 7 practitioners in the town.

Large and specialised though it is, it is still in general practice.

But at Marshfield personal medical care is a merely vestigial function, and we cannot look there for our shape of things to come.

Two Planned Experiments

From these illustrations of the natural process of specialisation I turn to two carefully planned attempts to develop general practice as part of a balanced medical service With support from Funds and Foundations, these experiments are being made in rural counties which had previously had hardly any specialists

---

[2] Baldwin, R. S. *Group Practice*, August, 1959.

The first is based on a hospital, the second on a private clinic

HUNTERDON

Hunterdon County, in rural New Jersey, with 45,000 people, had about 25 general practitioners and 12 public-health nurses, but no hospital and no specialists Farsighted citizens decided against having " just another hospital " and have cooperated to create one with teaching-hospital standards and progressive outlook which should be the county centre not only for medical practice but also for public health and teaching

With 120 beds, the hospital is staffed (a) by permanent specialists, of whom 17 are full-time, and (b) by almost all the local general practitioners The specialists, as faculty members of New York University, spend one day each week at the Bellevue Medical Center all their earnings go into a professional group fund from which they are paid (regardless of specialty) what is to all intents and purposes a regular salary The medical board is composed equally of specialists and practitioners, appointed by the board of trustees Some of the hospital's interns and residents are particularly attracted to it by the prospect of learning something about general practice, and a few students spend a month or two there " to gain an understanding of community medical practice "

As a hospital Hunterdon is outstanding its pædiatric department, where mothers have always been encouraged to come in and help,[3] is only one of many good things As a public-health centre it has had some successes but also setbacks it has not become the focus of local welfare services or of a county health department [4] But here I am concerned only with its effect on general practice

It has given the local doctors a diagnostic centre to which they can bring their patients examining and auxiliary rooms are used by all doctors alike (" we purposely want the specialists and general practitioners to be falling over each other ") It thus gives them and their patients the benefit of easy and personal consultation, and they also participate, if they wish, in weekly staff and departmental conferences In all this Hunterdon avoids " the two medical traps into which so many rural hospitals fall either they are medically mediocre because they lack specialists, or, if there is a specialist corps, it runs things at the expense of the voice, stature and potentialities of the family doctor " [5]

The facts of hospital life have to be faced, but all save one or two practitioners seem to be now content that patients admitted under their care are ultimately the responsibility of the full-time specialists, who make daily rounds and can offer suggestions That in the hospital the practitioner is no longer really in charge is shown by the following interpretation of his duties

> " He has a continuing obligation to the patient after his admission to the center, and he takes an active part in discussions concerning treatment. He thus maintains his contact with the patient and his family, writes orders, scrubs to assist in surgical procedures, if he so desires, and thus shares responsibility with the specialist on the staff for the selection and application of the best in modern therapy He attends medical and pediatric patients and makes uncomplicated obstetric deliveries The responsibility for normal obstetric practice is his, the role of the director being almost entirely advisory and, as the occasion requires, supervisory " [6]

This is a gallant and exciting experiment—at least partially successful But it leaves me with two doubts

First, if you have a hospital with not only full-time specialists but also residents and interns, can you continue to say that the patient's own doctor remains in any real sense in charge of him after his admission ? Having let the consultant take over his role as arbiter, the practitioner finds that his lesser role as the patient's attendant has to be shared with the intern or resident, and it is hardly surprising that, at Hunterdon and elsewhere, doctors admitting their patients have sometimes felt that, while helpful consultants are one thing, helpful interns are quite another Yet the intern, who is on the spot, can scarcely be blamed if he talks to patients, and he may easily seem to take too much upon himself Is the arrangement functionally sound ? Or should we not perhaps interpret these difficulties as showing that the bedside team becomes in fact too large and cumbrous if the practitioner is introduced as anything more than a welcome visitor ?

Secondly, what effect has this kind of attachment to a fine hospital had on the doctor's professional habits at his own " office " or surgery, five, ten, twenty miles from Hunterdon ? May he still, for instance, be seeing far too many patients in an afternoon ?

RIP VAN WINKLE

The second experiment—even more gallant actually—is quite different, and whatever shortcomings it may have it cannot at any rate be criticised for leaving the doctor's office unchanged, for it includes a direct attempt to upgrade medical work at the periphery Instead of leaving personal care to the individual practitioner, it aims at meeting the medical needs of a county through half a dozen widely spaced group clinics working in close relation to the centre

The story is at first not unlike that of other groups An able young surgeon was persuaded to come back to his home town of Hudson, in the small farming county of Columbia in New York State With a partner he started what became a clinic, and (known since 1946 as the Rip Van Winkle Clinic) this has a strong family resemblance to others I have described Very busy, and attracting some patients even from New York City, it hopes to move from its present cramped building to a site opposite the community hospital to which its members admit their patients It is a true group in that the members put private fees into the pool from which they draw their salaries, and the salaries have steadily gone up

What is chiefly remarkable, however, is that this clinic—a piece of private enterprise—is now conceived as the nucleus of comprehensive medical care for its county Already in three areas which have lost their doctor through death or retirement, the Rip Van Winkle Foundation has set up a small well-equipped clinic—two being in old houses while one is an exemplary new building The basic team in these clinics (when achieved) is to be two internists, a pædiatrician, and a dentist thus the doctors in charge are not general practitioners in the usual sense but specialists [7] They live in or near their clinic but visit Hudson, and they are in turn visited weekly by a surgeon and an obstetrician-gynæcologist Regular vans take people, equipment, and specimens to and from the centre

COUNTRY VERSUS TOWN

In the U S A , as in many other places, the young doctor does not readily go to work in the country The Hunterdon Hospital is trying to make rural New Jersey attractive by offering him the kind of diagnostic and therapeutic facilities he learned to use in his medical school, and an academic atmosphere The Rip Van Winkle Clinic is trying to make rural New York State attractive by likewise offering opportunities for really good work with some academic stimuli It enables young specialists to take such work without having to " assume responsibility in areas in which they are not comfortable ", and it offers a guaranteed salary and often a house from the start

[7] All the staff are Board-certified or Board-eligible in their specialty

To those who really like looking after people in their everyday life, and who like the country, these conditions may well seem almost perfect, and there are youngish doctors in the Rip Van Winkle clinics who seem ready to make general medical care their lifework On the other hand the scheme has not succeeded in incorporating the general practitioners of the county, and some difficulty arises from the fact that the doctors it has imported are all specialists The probable reason why the turnover of staff has been disappointingly high is that all these young doctors have been trained as internists and pædiatricians, not as general practitioners, and after a period in rural Arcady the young internist is apt to reflect that elsewhere he could be doing much more specialised work which would interest him more than the endless repetitions of local family care—and could be earning more money In a large city such as New York, the trained internist may be willing to do some general practice—as the price of staying where he wants to be But, if he goes to the country, he expects to work as a specialist

Though hindered by the young internist's tendency to move on, genuinely personal care is the aim of the Rip Van Winkle Foundation, and the clinic is unique, among other things, in being the only group under the Health Insurance Scheme of Greater New York (H I P) which offers prepaid medical care to individual families

Three H.I.P Groups

Of rather more than 3 million Americans whose general medical care is covered by prepayment schemes, about 550,000 are members of H I P At present, except at the Rip Van Winkle Clinic, these are all enrolled corporately as vocational groups (e g , all the employees of a firm who wish to join)—an arrangement that removes the risk of selection by " bad risk " individuals or families Almost all the care is given by 32 medical groups, which make their own arrangements within limits set by a medical control board, and provide (with loans or otherwise) their own premises or equipment H I P defines group practice as

> " provision of preventive, diagnostic, and curative medical services by family physicians, specialists, and other professional and technical staff working as a team in a group center, pooling their knowledge, experience, and equipment, as well as income "

It gives the group about 32 dollars a year (it hopes to raise this) for each person on their list and after the group have paid their expenses they distribute the balance among their doctors, as they think best, according to such factors as number of hours worked weekly in the group, number of years of postgraduate study, and length of service with the group

> " The security of an assured income and retirement program, the relief from discussing fees and from sending and collecting medical bills, and the knowledge that costs will not deter patient cooperation permit the H.I P physicians to be primarily concerned with the provision of good medical care " [8]

Groups have an average of about 30 doctors, of whom about half are specialists, with regular sessions, and half are family physicians Even the latter may do private practice, but the only charge they may make to H I P members for normal services is 2 dollars for calls requested and made between 10 P M and 7 A M On the preventive and welfare side, help is given to groups by headquarters consultants in health education and community resources The medical control board requires " a base-line history and physical examination for each new adult enrollee as soon as feasible after joining the medical group "

Only well-qualified doctors are appointed to the groups, and some 10 million dollars has been invested in the centres

As evidence of the advantages of the care it provides, H I P cites an inquiry showing that perinatal mortality (per 1000 live births and fœtal deaths) was 21 3 among its members compared with 30 1 for all private patients in New York City In another investigation, annual hospital admissions were found to be 77 4 per 1000 among H I P members against 94 8 among people who had similar hospital coverage but got their general medical care differently

I was able to see something of three of these groups

A CITY GROUP

The first showed how general practitioners in a group can fulfil their task without overwork, confining it to office hours

Originally a small specialist clinic, the building was rather shabby and cramped, but the doctors seemed friendly and consulted each other freely even about their private patients whom they saw on the premises The personal care was given by general practitioners, who had no offices of their own outside, and, though they had sessions at municipal hospitals, they could not take their H I P patients into these

Their elected chairman does not believe in overwork—" the tired doctor misses important signs "—and the hours are down to 35 a week with none on Saturday or Sunday From 8 A M till 7 P M one or other doctor is on duty for " house calls " (summons to the patient's home) after 7 these are taken by two competent and well-qualified outside doctors hired for night duty

The group preferred more leisure to more money, and did not mind confining their work to their clinic Boring? No they had their weekly session or two in hospital, and they met people when off duty They would be quite happy if the clinic were part of a hospital building To attach particular patients to particular doctors was unnecessary the group had been there some time and they were all known and trusted But they would have liked to be able to give more time to each patient

A SUBURBAN GROUP

The second group, far from the centre, was very different Here the general medical work was done b internists

[8] Daily, E F *J Amer med Ass* 1959, 170, 272

been virtually devastated in the process of becoming an inchoate suburb, without the traditions or stability of a community Already there is a large population, acquiring the "suburban neurosis"[9] Wives are housebound while their husbands have the car at work (they would not think of walking $1^1/_2$ miles to the shops with pram and children) What some of the doctors felt was an abuse of house calls was exacerbated because H I P members are spread over a large area, and the call may be from 20 miles away—the member being determined (some felt) to get her money's worth One doctor described his difficulty in avoiding the unnecessary use of antibiotics the patient thought he was being done down if not given them. Whereas the private doctor is suspected of giving unnecessary treatment so as to gain money, the H I P doctor is suspected of withholding necessary treatment so as to save it

From all its well-qualified young physicians this centre demanded (or had demanded) a difficult adjustment from specialised hospital work to general medical care—in a socially unattractive neighbourhood But its staff included several of the so-called redundant medical registrars whom H I P has from time to time recruited from Britain, and these required a further adjustment Every effort had been made to explain to them the disadvantages as well as the advantages of going to America[10] But the resemblance of the two countries too easily obscures the differences in culture American observers are astonished—indeed sometimes shocked—to find English patients so ready to accept their doctor and what he says to them in the United States the patient is far more demanding, and suspicious A relatively new arrival (much liked, I later heard) felt that in America he was treated less as a professional person he was called in to treat the body in just the way a garage man is called in to treat the car An experienced American colleague said "Perhaps it would be a good thing if the doctor could again talk to the patient with more authority" I noticed that though, in this clinic, the doctor's table was small and round, so that the patient could feel equal, a small arc of the circle had been inconspicuously cut away in front of the doctor's chair

A HOSPITAL GROUP

But the third H I P group is the most instructive, for it is really a hospital group, and shows how hospitals *could* take over most of the work now done by general practitioners

The Montefiore Medical Group, in a somewhat antiquated building beside the Montefiore Hospital, seemed to have a high morale they believed in what they were doing and enjoyed doing it

The 50 members (16 full-time) all belong to the hospital staff and can take their patients into hospital beds, where they have full responsibility for what is done Compared with the general practitioners at Hunterdon for example, the Montefiore group are in a far stronger position vis-à-vis interns and residents, because they are all recognised specialists Family medical care is provided by internists only, and the patient can be looked after by the same doctor in his home, in the clinic, and in the hospital bed The group's patients in the hospital are visited by group members in a "grand round" once a week

The group look after about 26,000 H I P patients and make a serious attempt to give them genuinely personal care The patient selects one of the internists as his family physician (children under 9 are looked after by a pædiatrician) and he does not see any other specialist except on referral from the chosen doctor The latter works 25 hours a week in his office, but he also has his hospital duties, and each night 3 family doctors, as well as a pædiatrician, and a representative of each specialty, are on call His income depends partly on the number of patients for whom he is personally responsible, but to all intents and purposes he is on a salary, since his remuneration can be calculated three years in advance He can see private patients at the clinic out of his office hours

The demands on this centre are increasing, but no more patients can be taken till it is rebuilt The new building will be physically part of the hospital

"The precondition for modern medicine in our group," says Dr George Silver, chief of the division of social medicine at Montefiore, "is a hospital-based unit, salaried physicians, a central unit record, supervision through meetings, communication between doctors, and some form of replacement for the family physician in the light of modern urban needs"

> "We recognize that the changing circumstances which have pretty much pushed the general practitioner out of the scene, at least in urban life, have not changed the situation under which the patient still wants and needs a family advisor, counsellor and guide"[11]

The internist equivalent of the "family physician" in the Montefiore group is unquestionably giving good medical care But he still cannot be said to meet all the patient's need for support and help outside the clinic An experiment has therefore been undertaken in which his contribution is supplemented by those of a psychiatric social worker and a public-health nurse—the three forming a "health team" which can offer a "new type of family medical practice"[12] Able to get specialised help alike from physical diagnosticians and from psychiatrist, psychologist, social scientist, or health educator, such a team can give advice, guidance, and support in the ordinary emotional stresses of the family Dr Silver is writing a book about this Family Health Maintenance Demonstration He describes it as *one* way of replacing the general practitioner of yesterday and today—whose demise, he feels sure, is only a matter of time

Home Care

That the Montefiore Hospital should be the scene of this significant sally into general practice is no mere chance, for the staff of this hospital have already made important excursions into territory outside their walls Though the institution which first undertook the medical care of patients in their own homes was the Boston Dispensary, which started in 1796, the modern type of home-care programme originated at the Montefiore thirteen years ago under Dr Bluestone[13]

Hospital beds are scarce and increasingly expensive, and a great many patients with long or chronic illnesses are happier in the beds they all of them have at home The object of the fifty-and-more home-care schemes now running in the U S A is to give such patients the essential benefits of hospital care without taking them out of their natural environment—except during acute episodes when this may be essential

Beth Israel Hospital in Boston, for example, has a team (physicians, nurses, psychiatrist, "physiatrist", occupational

therapist, social workers, and others) who give comprehensive care to people who no longer need be in hospital but are too ill to come as outpatients[14] Drugs and equipment are provided, and the patients are told to telephone the hospital at any time day or night if they want help

Though the programme was designed to benefit the patients —teaching and research being secondary objectives—it offers many opportunities for education, not only of medical students but also of nurses and social workers Participation in the home-care programme is an important part of teaching at the New England Medical Center, and at the Massachusetts Memorial Hospital it is regarded as the main clinical base for the department of preventive medicine

Home-care programmes are mostly restricted to people who cannot afford to pay a private physician, but some are already being extended to patients under their own doctor[15] As a Minor (or possibly Major) Prophet, Dr Bluestone sees this as a means of salvation for the family physician, for it is a way of bringing him into the organisational pattern of the hospital and into the centre of the circle of specialists where he belongs The hospital wall, Dr Bluestone says, must not be used as a barrier, or as an excuse for limiting hospital know-how to patients on the right side of it

> "The hospital must help the practitioner to solve the patient's problem in his own home wherever this is possible and desirable For this purpose, portable hospital equipment and skilled personnel which are now restricted to intramural patients must be made available to extramural patients, under conditions which leave the practitioner free to call on the hospital for either kind of service as required"[16]

The Mine Workers

To these examples of various patterns of medical care I add three from the services created for the United Mine Workers of America Counting dependants, the Miners' Welfare and Retirement Fund (financed jointly by employers and employees) is concerned with about a million people, and the development of its medical work —largely against opposition—is a phenomenon in American medicine In the large mining areas both hospital and general practice used often to be very poor contract practice with the workers at a mine was sometimes at a disgraceful level, and the injured could seldom hope for skilful treatment and reablement One step towards improvement was the simultaneous building of ten hospitals by the Miners Memorial Hospitals Association, while another is the establishment of specialised clinics and small centres for general medical care

1 *An Outpatient Department*

At Beckley in West Virginia the Association has an excellent hospital of 200 beds with a very capable full-time staff Its system of sterilising equipment has been studied by British visitors, and its arrangements for distributing food and stores to the wards also deserve attention. But its interest for me lay chiefly in the fact that it was a hospital trying to provide—mostly for miners and their dependants—much of the kind of care which is given elsewhere by practitioners

In a sense this was given at a high level, for the patients waiting in the crowded central hall were all seen by senior specialists Two of these attempted a little sorting, but all comers were then seen by one or other specialist in his own office On the other hand, though some at least of these physicians strongly believed in personal care, the outpatients' atmosphere seemed less conducive to this than a private doctor's office, and some of the patients, if better known to the doctor, would not have needed more than a glance and a few words I was not surprised that the medical director said that he would be glad if a couple of his internist residents with a bent towards general practice could be set up in a small nearby clinic where they could spare the hospital by doing some sorting

2 *General Care from Clinics*

The Bellaire Medical Foundation has a central clinic in an old house in Bellaire, Ohio, and a beautiful new one 12 miles away to which some of the staff go daily by car At least two of the internists are senior men—one being an authority on pneumoconiosis—but they all do family care Some of the staff have access to the local hospital, where the trustees are well disposed to the Foundation, and all the group do a grand round on all the group's hospital patients once a week. But, like quite a number of the groups I have described, they work under professional handicaps or medicopolitical difficulties, and their surgeon has had only three patients referred to him by an outside doctor

They attach some importance to keeping their own patients, and they are ambitious on the social and preventive side of their work, including periodic health examinations and the home service by which the Fund helps "independent living" by the disabled They hope to have a psychiatrist and a psychiatric social worker someday

Their morale was high many of the staff, and a lawyer trustee, gave me a lot of time on a Sunday afternoon and evening

3 *A Centre with Peripheral Practices*

If Bellaire was particularly interested in general medical care, Centerville in West Virginia was specialist-oriented. Primarily a consultation centre, it was bursting out of its quarters in a converted farmhouse and barn, and an additional large building was in construction Patients needing admission were sent to one of three small community hospitals in the neighbourhood.

This clinic was a lively professional centre for local practitioners working for the Fund, and it hoped they would come in twice a week for consultation or meetings I visited two of the peripheral practices In one a practitioner, who was also a playwright, worked solo from a miners' meeting-hall, which had been turned into an austere but tolerable surgery, while in the other a couple of doctors (both new to the job but perhaps all set for dedicated practice) were installed in a well-equipped centre next door to the mortician—a variant on the more usual plan by which the doctor has a drug-store as his neighbour

Two Questions

At clinics where general medical care was given by internists I sometimes asked two leading questions

These men having trained as specialists in internal medicine, I asked them whether they would accept an opportunity of full-time work in that specialty Their answer usually, though not always, suggested that their heart was still in hospital medicine rather than in personal practice

Secondly, I asked members of the group whether they would like their clinic to form part of the buildings of the local hospital Here the reply was, in the words of *My Fair Lady*, "Wouldn't it be loverly?"

SPECIALISATION

Much of modern medicine can be practised only by specialists, and, to complement one another, specialists must work in groups The farther their specialties diverge, the larger should be their group and the closer its integration

---

[14] Sheps, C. G Address to A.M.A. Regional Conference on Ageing, Boston, Sept 17, 1959 Also annual reports of hospital's department of home care

[15] Bluestone, E. M *in* Long-Term Illness (edited by M G Wohl), p 27 Philadelphia and London, 1959

[16] Bluestone, E. M Letter to members of Hospital Administrators Correspondence Club, 1955

Nearly always the best place for specialist work is a hospital, and, though some of the American groups I saw were what Dr Silver calls " rootless ", I am sure the bigger ones will end by moving into hospital premises, where they properly belong I do not say that a small group of specialists cannot work at a distance from the hospital to which they are attached, but, if they do, they will tend to think of themselves as an outpost, an outpatient department, even a sorting-station

My own opinion therefore is that if, in any country, the general practitioner is replaced by a group of doctors trained to regard themselves as specialists, the result will eventually be provision of general medical care by and from the hospitals The experiments I saw in the United States seemed to be leading in that direction, and, though they were atypical, they would probably not have existed if the American public had not accepted medical specialisation more fully than the public here The more sophisticated and affluent Americans tend to bypass the practitioner, making their own provisional diagnosis and going straight to the appropriate expert

> " I called my group this morning, told them I had a bad rash and asked to see the skin specialist This girl on the phone tells me I've got to see my family doctor first What kind of a run-around is that when I need a skin specialist ? "[17]

Among the Americans who set fashions, the majority might well think that medical care from the specialists of a hospital clinic would be the best possible

Would they be right ? Certainly the clinic or group can give its patients the benefits of specialist advice and treatment without the risk (and expense) of " shopping around " and it will often work at a higher technical level than the outside practitioner The task of sorting patients and giving general medical care is ordinarily entrusted to an internist or general physician—whom Esselstyn[18] describes as " the keystone of group medicine " Whereas many independent doctors have time only for symptomatic medicine, this group internist is expected to reach a working diagnosis, and has facilities for reaching it

As I have hinted, there can be certain practical difficulties about this upgrading of general care Patients who drop in for a few words or a few pills may be none too pleased to find themselves given " the works ", and their request for a check-up may be taken rather more scientifically than they intended Moreover, extra time, from a specialist with a shorter practising week, has to be paid for In principle, however, the patient clearly stands to gain a lot from entrusting himself to a specialist physician

The question is does he not often lose a lot too ? Are a specialist group, or any members of it, going to give him the *personal* care that means so much to so many ?

PERSONAL OR IMPERSONAL ?

No plans for the future are realistic unless they take full account of people's need for personal as well as specialist care The two kinds overlap, of course. Some specialists (pædiatricians and geriatricians, for instance) practise personal medicine nearly all the time, while nearly all specialists practise it some of the time a man does not cease to be a good doctor because he is a urologist or a pathologist But the specialist is, by definition, called on to solve some particular problem, and he may reasonably be reluctant to cope also with the patient as a person It is no accident that the man who is " Mr Jones " to his own doctor should so often become, in hospital, " the hæmatemesis in the end bed "

Many doctors and nurses spend much of their time in preventing this depersonalisation of hospital patients—especially perhaps in the United States[19] But in any large institution depersonalisation is a natural process which can be mitigated but can seldom be abolished It is all too evident, for instance, in most hotels

> I remember that when I paid my first visit (rather shyly) to the most famous of London hotels, I was astonished not by the splendour of the surroundings or the food—each readily equalled elsewhere—but by the natural not-at-all-superior manners of the staff, who gave one unhurried personal care What the rich were paying for (I suddenly realised) was simply the pleasant easy atmosphere of a private house

Nowadays most hotel-keepers are well aware that people like to be treated as people not as admissions But big institutions always develop needs of their own which are apt to take precedence over those of their users, and only the very good hotel or the very good hospital gives its clients the sense of personal attention they would expect in a wayside inn or a doctor's consulting-room, surgery, or office

If specialist care is the primary task of the specialist and the group, personal care is presumably the primary task of the individual practitioner In real life, this fundamental distinction is often blurred, for, whereas many specialists give their patients not only specialised but also personal help, some general practitioners do not fulfil their particular function A London consultant was saying to me the other day that, though in principle he favours consultations at which the practitioner contributes knowledge of the patient's history and background, he finds that many patients have never had a chance to tell their story until they reach the specialist One explanation is that the practitioner has less time than the specialist, but often he has less inclination or has an impersonal outlook on his work If he thinks of himself as a sorting agent rather than as his patient's real doctor, he feels his duty fully done when he recognises a possibly significant symptom and hands the case to an expert

THE FINANCIAL EXPLANATION

In this country failure by a practitioner to provide personal care—to take full responsibility for his patients and form a strong personal relationship with them—is usually put down to circumstances he is usually looking after too many patients, and, because he is paid by a capitation fee, he has no financial incentive to take trouble over cases that a specialist will accept Superficial, perfunctory, impersonal practice is attributed to " the system ", and at first sight this convenient explanation gets some support from American experience

---

[17] Weltner, G H, Lear, W J Subscriber Attitudes in H I P Paper read before American Public Health Association, Oct 20, 1959

[18] Esselstyn, C B *New Engl J Med* 1953, 248, 488

[19] I found that, as a doctor visiting wards, I was carefully introduced to patients, with names all round An American doctor told me how horrified he had been in an English hospital when a registrar had taken him to see a patient and without introducing him had unrolled the sheet and shown him her leg He had been equally shocked by the impersonal character of a ward round by a physician—who happens to be a friend of mine and a most humane man

Even before I landed I was told that one of the big schemes of prepaid medical care, provided by groups, was progressing relatively slowly—because "people don't like it, they feel that they don't get the care and consideration they have from a private physician." In this scheme the doctors are paid a kind of capitation fee that amounts to a salary, and, though they are a carefully selected body of men and women, an experienced observer agreed that their attention to patients was in fact less personal. This he explained by the way they are paid:

> "It's a sad fact," he said, "that when you remove the direct financial bond with the patient—the fee for each service rendered—many doctors become less interested, kind, and sympathetic. A proportion *need* this financial relationship."

In New York's H.I.P. the most common complaint relates to the physician's "attitude" ("Dr. —— was very impersonal. Never a hello or goodbye").[19] Unhappily, in American prepayment schemes as in the N.H.S., the occasional patient wrecks the professional relationship from the start by claiming his "rights."

On the other hand, the fee-for-service system does not necessarily ensure personal attention: one of my lay informants commented bitterly on the mechanical production-line methods of a doctor whom he was paying. For my part I regard this system as a professional hang-over, and I hope that, as an alternative basic source of income, the capitation fee will prove more generally acceptable when it becomes larger and doctors can have fewer patients. But difficulties arise with *any* system of paying doctors, and I believe that, as a source of personal care, the American specialist group has a more fundamental weakness than lack of financial inducements to kindness.

LIMITATIONS OF GROUPS

The truth, I fancy, is that a large group can hardly ever perform a personal function really well.

Even a small group has difficulty in doing so. Thus Nourse,[20] though happy in having joined three specialists to form what he calls a "composite family doctor", says that "strive as they may, no group of doctors can completely substitute for the personal touch of the old-time family doctor, for the reliance of the patient upon one individual for wisdom, counsel, friendship and help." He begins his admirable article by quoting an indignant young man whose wife had gone into labour early, when Nourse was away duck-shooting, and had been delivered by a partner:

> "What's wrong with you doctors, anyway? You aren't like you used to be. You don't really care what happens to your patients, you charge twice as much as you ought to, but when somebody needs you he can't ever find you! What's become of the kind of family doctor we used to have?"

Nourse thinks that his group is giving far better medical care than "the inadequate, sentimentalized image of yesterday", but he hopes that we shall not discover too late that part of what we have lost is irreplaceable—"the feeling of warm personal regard and concern of doctor for patient, the feeling that the doctor treats people, not illnesses, and wants to help his patients not because of the interesting medical problems they may present but because they are human beings in need of help."

What Nourse says about his group of four applies, a fortiori, to a group of thirty. In theory, personal medical care of the highest quality will be given: the internists who give it will perhaps have their own list of patients and may look after them for years. But I am pretty sure that in reality any member of such a group will sooner or later come to think of his patients mostly in relation to the clinic and hospital, not in relation to their work and home.

In retrospect I am impressed by the infrequency with which some of these internist-practitioners made home visits: in one group, for example, the normal number was about 5 a day. The explanation given was significant: the home, I was told, is usually a very bad place for examining anybody—you can't move the bed, the mattress sags, and there's incessant conversation and scuffling around. So the patient had better come to the clinic or hospital where one can really find out what is wrong.

Well, of course, this is the point of view of the doctor who has been trained to think in terms of disease in hospital rather than about people in the middle of their families. Surely, if you really want to get to *know* somebody, there is nothing like visiting his home, where much will always be revealed. If I wanted to discover whether a doctor had a vocation for personal care, I should begin by asking what he thought about house calls. After that I should inquire into his attitude towards the unnecessary, and often maddening, visits by which so many patients seek to form, or keep up, their acquaintance with their doctor.

Though, for myself, I should cheerfully register with the internists of the Montefiore Hospital Group—who were friendly, helpful, and competent—I do not think even they would claim to be able to give me all the kinds of help I might want as personal care. That is why Dr. Silver has undertaken the experiment I mentioned, in which the work of the internist is supplemented by that of a public-health nurse and a psychiatric social worker.[12] This is his way of compensating for the group's natural tendency to look inwards towards the hospital instead of outwards towards the home. And no doubt it will work very well up to a point. But I am not yet persuaded that any amount of compensation or ingenuity is going to make a hospital staff—or any group of specialists—the right people to give the public personal medical care. The public, I fancy, will get it better from doctors who are primarily interested in providing it, and who do most of their work at a distance from the hospital.

Hospitals are the fortresses of medicine, and should be used as the second and third lines of defence. The first line should consist of numerous well-sited posts manned by lightly armed but versatile and mobile troops, trained to use their own judgment.

I know, of course, that personal medicine must be more closely related to specialist medicine than it often is at present, but I am pretty sure that the personal doctor should preserve a measure of geographical and psychological independence from the specialists and their elaborate institutions.

TITLE AND FUNCTIONS

What kind of doctor do we want, and what is he to do? Perhaps we shall know the answer better if we find him the right name.

GENERAL PRACTITIONER?

In thickly populated countries like Britain the truly general practitioner is extinct: indeed, few of us have ever seen one. In relatively inaccessible places elsewhere, including parts of the United States, there are doctors who do virtually everything that has to be done for their patients, and some of them would deplore any constriction of their work (I heard of a hospital in the backwoods where none of the seven local doctors could be dissuaded from doing all his own surgery—because his patients expected him to provide full medical and surgical care and he would lose face if he proved less than omnicompetent) But all over the world the lights are going out on that kind of general practice Proper and necessary in an isolated countryside, it is improper and unnecessary where the patient with a difficult disorder can have this treated by a specialist And even in the United States 57 5% of the population last year were already living in the large towns which are designated standard metropolitan areas[21]

---

[20] Nourse, A. E. *Saturday Evening Post*, Oct. 17, 1959, p. 25.

Because specialisation is an inescapable part of medical progress, the trustees of more and more American hospitals are ruling that only specialists shall operate, or do obstetrics, or even have admission rights, and the result in cities is that the general practitioner's practice grows palpably less general Against this trend the Academy of General Practice is fighting a rearguard action Though some of its 25,000 members may be partly interested in preserving lucrative occupation, the Academy has done much to improve morale and raise standards among practitioners, and it believes (as I do) that something very important to the public will be lost if what remains of general practice is taken over by the Man from the Hospital But has it really chosen the best ground for its stand? Nowadays the argument that a qualifying degree gives the doctor a right to do any kind of medical work is quite out of date we all know that occasional surgery or midwifery is even more dangerous than occasional motor-driving, and unless people are fully competent to do things, and keep themselves in practice, they have no right to do them at all—whatever degrees or tests they took The Academy, surely, should recognise that truly general practice, except in remote areas, is already finished, and that most of its members are very sensibly doing something far less ambitious and terrifying

But perhaps their residue of activities includes something enormously worth doing which no hospital or specialist group can do so well? I believe it does, and I think the Academy should be less interested in its members' questionable right to do obstetrics or omphaloscopy and more interested in their qualifications for giving good personal care

The point at which to call a halt in the process of erosion of general practice by specialists is the point at which the practitioner would no longer be in a position to do this vital part of his job

FAMILY DOCTOR?

Now that many so-called general practitioners no longer do obstetrics, advise on babies, set fractures, sew up lacerations, test eyes, or prescribe for diabetics, their title is patently obsolete Devised for an Act of Parliament, it was always chillily official, and now it is inaccurate As a designation for what Stevenson called " the flower (such as it is) of our civilisation," G P is even worse

Family doctor or family physician, with its friendly warmth, is much better It suggests continuous care of parents and children over the generations (" I brought your mother into the world ") and the experience of medicine and of life that this can give But as a description of doctors who seldom look after whole families, and whose patients are always moving to another job in another town, it represents an aspiration rather than a fact In England, in the three years 1948–50, 13% of the population moved from one local-authority area to another and, as for the Americans, they are " almost a race of nomads "[22] one person in five changes not only his home but his State of residence every year[23] And even when they stay in one place, members of a family often have different doctors

When an American family has young children, the person who often comes closer than anybody to being the family doctor is the pædiatrician, for in the United States, as in Russia, most pædiatricians do a kind of general practice among children, and relatively few are consultants

PERSONAL DOCTOR?

The doctor we have in mind, then, is no longer a general practitioner, and by no means always a family practitioner His essential characteristic, surely, is that he is looking after people as people and not as problems He is what our grandfathers called " my medical attendant " or " my personal physician ", and his function is to meet what is really the primary medical need A person in difficulties wants in the first place the help of another person on whom he can rely as a friend—someone with knowledge of what is feasible but also with good judgment on what is desirable in the particular circumstances, and an understanding of what the circumstances are The more complex medicine becomes, the stronger are the reasons why everyone should have a personal doctor who will take continuous responsibility for him, and, knowing how he lives, will keep things in proportion—protecting him, if need be, from the zealous specialist

Continuity of personal care is the ideal, though admittedly unrealisable unless both patients and doctors are willing to stay in one place If there were a really good system of recording and documentation by which essential data were passed from one doctor to another, the fact that the doctor changes would matter less than formerly Indeed Professor Rutstein points out that the disadvantages of personal discontinuity could be offset to some extent if everybody carried around a Lifetime Health Record[24]—which would undoubtedly be more reliable in some ways than the old doctor's memory

Of course he is right—though in Britain most of us still think medical notekeeping by patients a morbid pursuit, to be discouraged I know, too, that we must get used to a world in which ices no longer taste of cream, nor new potatoes of new potatoes, and in New York those ghastly plastic flowers seem to be commoner than real ones But nobody is going to persuade me that a nice receptionist, some good notes, and an internist keeping office hours add up to a personal doctor who knows me and my home Even if you throw in a psychiatric social worker, I still feel that I am being put off with a plastic substitute for the real thing And I am supported in this belief by the knowledge that when personal medical care is abolished it is sooner or later reinvented

[24] Rutstein, D D Lifetime Health Record Harvard University Press, 1958

Thus, even under the Soviet system, the Russian leaders have personal physicians[25] It is the natural and sensible thing to do, and they can afford to do it So should we

THE PERSONAL DOCTOR

The personal doctor is of no use unless he is good enough to justify his independent status If (like many unqualified healers) he has a therapeutic personality, that will be a great help, but in any case he needs to have the knowledge that comes of a continuing interest in medicine, together with trained and critical judgment

DIAGNOSTICIAN

If he is to take responsibility he must feel that *he* is the patient's doctor and he will never feel this unless he tries to make his own diagnoses—as fully as his facilities and time allow Examination of patients is necessary because, as everybody knows, the fatal mistakes are made not through lack of knowledge but through lack of care But my point is rather different It is that the doctor who fails to examine and diagnose has lost his right to be an independent personal practitioner Experience may well have made him skilful and very useful in dividing the serious from the trivial, but, if he does no more than this, he is working as a preliminary sorter or feeder for the hospital, and he may as well do it as a peripheral and junior member of the hospital staff To be a personal doctor one must remain a real doctor, and not turn into the manager of a practice

TEACHER

The personal doctor must also be a teacher, not only in showing people how to avoid disease but in showing them how to live with their disabilities—physical or mental These things are not done at a single interview at a clinic I was deeply impressed by an experienced pædiatrician in Wisconsin who said that when a mother is troubled about some deviation in her child, she may need reassurance not once but again and again Nobody, he felt, could give such help as the physician who saw the children, year after year, well and ill, removing or at any rate sharing the parents' anxieties and burdens And nobody else was so well placed to prevent those recognisable mistakes of upbringing that so often lead to emotional disaster

PSYCHIATRIST?

On the topical question whether the personal doctor should train himself in psychotherapy, I shall say no more than this—he must allow people to talk Often a patient and sympathetic hearing is all that is required to give someone insight and a fresh start Yet doctors everywhere have become so busy that they commonly deny the patient what he wants most

"No time," of course To which the obvious retort of the simple-minded public is "Why, then, do you say you have too many doctors already? Why not have more?"

DIVISION OF LABOUR

The public is right there are too few doctors for the work to be done Nevertheless there may sometimes be too many for the money available to pay them Whereas Russia has met her medical needs by mass-producing doctors who are none too well qualified and worse paid, the profession in Britain intends to keep up its standards

One alternative to having more doctors is to make better use of those we have—by giving them ancillaries to do everything the doctor need not do himself The logical development of this is that the practitioner of the future will be the leader of a team in which nurse, receptionist, secretary, health visitor, and social worker relieve him of many things he used to do Thinking in terms of a *general* practitioner, this solution seems sound, and certainly we want doctors of high quality whose skill is used economically and who make use of other people's skills But if our object is to provide the right conditions for a *personal* doctor, we must beware of carrying this division of labour too far If somebody else is to do all the small things for the patient, under the doctor's distant supervision, personal contact will be reduced to a minimum, and if this happens, the patient might just as well go to the hospital Unquestionably the practitioner needs helpers in his surgery or office, and should be able to call on a wide range of skilled ancillaries outside, but the particular object of his independent existence may be defeated if he leaves all dressings to the nurse, sympathy to the receptionist, messages to the secretary, and the solution of home problems to the social worker Organisation can be a menace to the personal care we are supposed to be organising

Again, for personal care to be a reality, free choice is necessary, and there should be quite a few doctors to choose from

I see that van der Wielen,[26] after a detailed study of practice in Holland, gives 2000 as the maximum number of patients that a doctor should have on his list, and if we are really to aim at good personal care—and stop the drift towards wholly hospital medicine—we shall have to think again about the number of doctors needed to give it Is our country really incapable of using all the doctors it trains—or even of finding and training and paying more, of the same or a higher standard?

HOME OR HEALTH CENTRE?

Where should the personal doctor work? Ideally, I would say, he ought to work in his home—like his archetype, the genuine family doctor of yore For establishing a lasting personal relationship there is nothing better than seeing the patient in his home or yours But doctors, like other people, usually want to retain their wives, and if they are to do this, most of them will nowadays have to have their surgery, consulting-room, or office at a distance Even so, it should not look like a shop, an office, an outpatient department, or a mortuary it should look like an extension of the doctor's home Some doctors could make their patients feel like personal friends if they received them inside a refrigerator, while others can make them feel like personal enemies in the warmest and most cheerful surroundings But because human qualities can triumph over environment, it does not follow that a place that looks like the bathroom is as good for personal doctoring as one that looks like the master's study

Agreement that what is wanted today is not a general practitioner but a *personal* practitioner could make a big difference to the kind of buildings from which doctors work Many of us were reconciled or attracted to the National Health Service chiefly by the promise of a new deal for the practitioner, who was to have all the help he needed to do better work in better quarters—the health centre Personally I thought that the kind of health centres then proposed would be a success, and I still regard the failure to experiment with more of them as inexcusable But I now suspect that they were wrongly conceived

---

[25] Field, M. G Patient and Doctor in Soviet Russia Harvard University Press, 1958

[26] van der Wielen, Y De Huisarts en de Doeltreffendheid van zijn Aandeel in de Gezondheidszorg (The General Practitioner and the Effectiveness of his Share in the Care of Health.) Gezondheidsorganisatie T N O Assen, 1960

There are, I have suggested, only two kinds of care—personal and specialist The best place for the first is the doctor's home, or some equivalent of it, while the best place for the second is the hospital For the health centre—a new kind of intermediate institution—I can see no function If visited by specialists, it could be useful as an extension of the hospital, but as an extension of the doctor's home it is unconvincing A building which looks like an institution, or is so large that it has to be organised like one, may be a good place for getting the benefits of modern science or civic aid, but it is not the place for finding one's *own doctor* The skill of interior decorators, though it may make a modern medical centre quite charming, very seldom disguises the fact that the doctor's room is not his own Three photographs of the children, and some pink-foot geese by Peter Scott, are Not Enough

SOLO OR GROUP ?

The doctor we all want to have looking after our families and ourselves is always at home and always ready to cope he is never off duty and never on holiday That is the patient's ideal, and such people do exist A young practitioner in North Carolina complained that old Dr J had spoilt the neighbourhood he had had no interest whatever outside medicine, and had always been cheerfully on call, day or night

But, though we should like our doctor to be always on hand, we also want him to be a well-balanced man with a life of his own—not a tired obsessional He must have leisure and recreation, and the only way in which he can get them and maintain a twenty-four-hour service is to have assistants, or partners, or colleagues who stand in for him Though there are doctors who still prefer solo practice, the general tendency is towards association Whereas before the start of the National Health Service, about half the practitioners were working singlehanded, the proportion now is less than a third [27]

The group thus formed may do one of two things It may do its utmost to preserve the personal relationship though the patient may have to see a partner, he belongs very definitely to his own doctor Or it may try to make him feel that he is the patient of the group rather than of any individual Thus in an American practice a card for patients said

> “ To render good medical service on a 24-hour a day basis, we three general practitioners operate as a group practice We would like for you to feel that you are a patient of *all three* physicians rather than any specific one and to feel free to consult any one of us about your health problems as they arise ”

Where there are only three partners and they work together for years, there is admittedly a good chance that patients will establish a pretty strong personal relationship with all of them But what happens when this group enlarges, or takes in members who do not stay ? Wherever a partnership exceeds two or three, or ceases to observe the one-patient one-doctor rule, its feet are set on the slope that leads from personal medicine to group medicine, and the proper place for group medicine is the hospital

In countries like England, where specialist services are well developed, all that the patient needs outside them is the care of an individual doctor Formal or informal association with one or two others of his kind will help the personal doctor—not only because it gives him leisure, and a chance of doing some specialised work on the side, but because he can talk about his cases to his colleagues over coffee But there is, I suggest, no functional advantage in having any larger or more complex group, which is liable to turn into some sort of “rootless” clinic

SPECIAL INTERESTS ?

An essential feature of the kind of small partnership I am advocating is that all its members shall be primarily personal doctors It is thus entirely different from the “ composite general practitioner ” described by Nourse, [3] in which the functions of the old general practitioner are fulfilled jointly by (let us say) an internist, an obstetrician, a surgeon, and a pædiatrician working together That resembles the Russian model for the countryside (except that the specialists are far better trained), and it is based, in Russia as in America, on the obvious fact that no one man is competent to undertake all kinds of practice at a modern level But what may still be right for isolated places in the U S A or U S S R is wrong for Britain, where nobody is very far from hospital No longer needing truly general practitioners, we do not need their composite modern equivalent either We need doctors with different, though equally important, terms of reference

But though I believe that in Britain all specialised work should be done in, or under the auspices of, the hospital, this does not mean that no personal doctor should do any of it On the contrary, it is necessary that the personal doctor with special interests should be able to follow them —partly because he must not feel unduly restricted in the practice of his profession but also because the two sides of medicine—personal and specialist—need to be linked by people who are engaged in both

But there is a vital condition on which alone this should be done—namely, that the personal doctor who wants to practise any specialty must join the appropriate specialist team of a hospital As personal doctor he is an independent practitioner, professionally the monarch of all he surveys, but in so far as he decides to be also a specialist he must accept the leadership of the whole-time specialist at the hospital Under the National Health Service final responsibility in any specialty must rest on a consultant and not on a part-time specialist

Taking the largest and fiercest bull by the horns, I say firmly that this rule applies to obstetrics The delivery of infants is unquestionably part of general practice, but, as I have tried to show, general practice is dead or dying in this country To my mind at least, obstetrics belongs to specialist medicine rather than personal medicine—to “ episodic ” medicine (in Dr Iago Galdston's phrase) rather than “ maintenance ” medicine Some might say, of course, that if the practitioner has to act as agent for a specialist when he looks after a woman in labour, he must equally act as agent for other specialists when he looks after a child with asthma or a man with angina On this argument, if he loses his independent status in obstetrics he loses it in everything But in real life, surely, there is a substantial difference between the two kinds of work In his management of asthma or angina the doctor may need specialist advice, and in a crisis he may have to send the patient to hospital But nowadays he cannot properly practise obstetrics *at all* without a specialist organisation at his back, and, since it may have to cope with results, that organisation is entitled to lay down rules—e g , about antenatal care Hence there are particularly strong reasons, I would say, why the ultimate responsibility for all maternity work in an area should be borne by consultants Many practitioners who are primarily personal doctors are extremely good at this work, and they should go on doing it, but if they deliver babies—whether at hospital or in the home—they should do so as members of the obstetrician's team

---

[27] Godber, G E *Lancet*, 1959, ii, 224

The obstetric bull being now (I trust) removed from the arena, I come to a more general pronouncement—namely, that when a man in personal practice finds that his mind is really on a specialty, his move into hospital work should be made easy by opportunities to gain the needful qualifications Though personal and specialist practice should be clearly distinguished, the difficulty that people nowadays have in transferring from one to the other is wrong Our system is far too rigid

RELATIONS WITH THE HOSPITAL

Outside the specialist services, the personal doctor is in full charge—responsible and independent Only when we are sure that this independence will be recognised and safeguarded can we go on to consider the equally important *inter*dependence of the two kinds of medical care Unless they are hand in glove, the patient must suffer

COMMUNICATIONS

At the most elementary level is the obvious need for really good communications between personal and hospital doctors [27, 28]

Even in America, hospital reports and letters often come late there are delays in dictating, and typing, and signing, and posting One answer to this is that, since we have to live in the modern world, we should make more use of its convenient inventions A big advance in medical civilisation would be made almost overnight if every hospital in this country followed the example of the, Massachusetts General Hospital in urging housemen to use the telephone freely Without regard to distance, they are encouraged to ring up the doctor if they want more facts when his patient is admitted, and always to inform him fully before the patient is discharged

Equally, of course, the practitioner has a duty of communication, in which he too often fails—in America as here Thus in nearly 60% of cases attending a university consultation centre no medical information was sent by the referring doctor [29]

MEMBERSHIP OF STAFF

Provided they undertake to provide such information, all personal doctors should, I suggest, be made associate members of the staff of the hospitals with which they work. As such, they would have free access to any of their patients who are admitted, and on such visits their help would be regularly invited They should be welcomed, too, on any ward round, they should have full use of the library, and there should be at least one comfortable room which they could regard as their home in the hospital and where they could meet their specialist colleagues Already some hospitals try to serve as a kind of club for the doctors of the locality, and the gain, though intangible, is out of all proportion to the cost

I see the associate members of a hospital staff as comparable to graduates who keep their names on the books of an Oxford or Cambridge college. They are not fellows, and they take no part in college government, but as members of the college they may have the right to dine in hall, and they are always received as people who " belong "

" DEPARTMENTS " OF GENERAL PRACTICE

The American Academy of General Practice goes much further it wants all large hospitals to have " departments of general practice " on a par with the departments of medicine or surgery Except that it may sometimes look after the outpatients, such a department has no clinical service of its own, but it gives general practitioners a voice in hospital administration and opportunities to meet as a group intent on raising standards—by self-criticism and self-discipline

The Academy is trying to preserve much of the old *general* practice, and the hospital has to allow members of these departments to practise general medicine, pædiatrics, obstetrics (" to include low forceps, episiotomy, cervical and perineal repair "), and surgery (" as it applies to the care of wounds and reduction of simple fractures ") [30] If they wish to go further in a specialty they must satisfy a credentials committee and will then be under the jurisdiction of the chief of the clinical service in which they work

OFFICE AT THE HOSPITAL ?

A rather different but notable experiment is being made at the New England Medical Center in Boston, where three practitioners have been given an office in the hospital They still have their private offices outside, but at the hospital they can see cases for which they might like specialist investigations or opinions The object, Professor Proger [31] explains, is to combine the advantages of individual and group practice in his own community the practitioner functions as an individual family doctor, while in the Medical Center he functions as a member of a group

This scheme has much in common with the one at Hunterdon Hospital (see p 746), to which all the local practitioners can bring their patients for examination and consultation But in this Boston teaching hospital the purpose is more widely educational Not only does the practitioner gain, but so do the students and interns A student working in the family doctor's office " would be getting not outpatient work that imitated office practice, but actual *office practice* " and the scheme gives the hospital a chance to develop a home-care programme for students that " would *be* private practice in the patient's home " Through the family-doctor unit, Dr Proger hopes, medical practice in the area will be directly influenced by the standards of the teaching centre

---

[28] *Lancet*, 1959, ii, 219

[29] Williams, T F , White, K L., Andrews, L P , Diamond, E , Greenberg, B G , Hamrick, A A , Hunter, E A Paper read at annual meeting of American Public Health Association, Oct 19, 1959 Other interesting findings in this study were that about half the referrals were initiated by the patient rather than the doctor, and that over half the patients did not go back to see their doctor within the next month or two

"GENERAL PRACTITIONER BEDS"

Like the American Academy of General Practice, I am sure that the personal doctor, when so inclined, should undertake specialist work—either in hospital or in a specialist service outside it (e.g., maternity). But the kind of associate membership of the staff that I want him to have would not entitle him to do this: he must also hold a specific appointment which attaches him to a hospital department for which a consultant is ultimately responsible.

The rule is plain and we must stick to it. Outside the hospital services the personal doctor is in charge: inside them he is an agent for the specialist.

Thus, if he is to look after patients in any kind of hospital bed, he should be appointed and paid for the purpose by the hospital. But I hope that, so far from being an exceptional arrangement, this will become very common. Hospital boards ought, I believe, to provide many more beds where practitioners can deliver their patients, and treat the less serious illnesses, under the auspices of a consultant. In the countryside these auspices might be rather remote, and usually the practitioner would use his own judgment. But I do not think that this would restore the abuses sometimes seen in cottage hospitals in the old days, and sometimes still seen in America. In doing this hospital work as an appointed member of the consultant's staff, the practitioner would have strong reason to seek advice, instructions, or other help whenever difficulties arose: indeed there would be good hope of the frequent consultation which can be so informative to both sides. Stallworthy [32] has lately made the excellent suggestion that practitioners should, *in the same way, staff the hospital annexes to which patients should be transferred as soon as they can safely leave the ordinary wards.*

American observers often say that the British practitioner's status as a doctor, and his morale, must have been damaged by depriving him (so often) of his hospital beds. Though the classical study of general practice in North Carolina [33] revealed no difference in the quality of care given by doctors with hospital associations and those without, I suspect that these American observers are right: to maintain their enthusiasm and their interest in medicine, some doctors require the stimulus of looking after illness in hospital, while almost all of them require the stimulus of frequent contact and conversation with colleagues. Though a proportion can get full professional satisfaction from purely personal medicine—and perhaps the proportion will grow—it is very important that anyone who feels the need of hospital work should get it readily.

HOME CARE

If very early discharge from hospital becomes the rule, the practitioner will be taking over some of the hospital's work—for which, indeed, it might properly pay him a fee. Even so, his patient's return home means that he must resume full responsibility, seeking hospital help only when he needs it.

But, though the hospital must be careful not to invade the personal doctor's territory, its special services should always be at his disposal. Where he is working as a peripheral member of a hospital department, as in obstetrics, he can of course command the help of his departmental colleagues, in the form of a flying squad if need be. But there are other aids to home treatment, such as the visiting pædiatric team,[34] which should have further trial, and at all times home consultations with specialists should be encouraged. These arrangements would go a long way to satisfy Dr Bluestone's plea that the hospital should sustain the practitioner, but in Britain the hospital need not ordinarily supply him also with nurses or equipment or social workers or domestic helps. In this country these come from the health department.

RELATIONS WITH LOCAL AUTHORITIES

In the U.S.A., where private enterprise gets so much honour (and often deserves it), the public-health authorities have been very cautious about taking any part in curative medicine. Their attitude is slowly changing, under the leadership of such men as Dr Herman E. Hilleboe, health commissioner of New York State, who says:[35]

> "… both preventing and ameliorating disease and disability is the business of everyone in medicine. … The function of a public health physician is to perform public health services that require organized community action. This may be preventive, diagnostic or therapeutic. … The function of a general practitioner is to perform any private health service that his patient needs. This, too, may be preventive, diagnostic or therapeutic. Both the private practitioner and the public health physician may perform these services directly or by referring the patient to another medical specialist.
>
> "All this may seem like a rather simple way of straightening out a fallacious bit of reasoning which had as its faulty premise: Public health equals preventive medicine. The truth is, it has not been easy to clear up this misconception. … what is emerging is a general recognition that a close partnership between public health physicians and general practitioners is vital to the welfare of the people in every community."

In Britain, happily, many medical officers of health have long cooperated with practitioners in providing personal services. Developments at Bristol under Prof. R. H. Parry were a notable early example.

That the personal doctor in this country can increasingly look to the health department for aid in his work is, I believe, a good thing because it counters any tendency of practitioners to think too much in terms of hospital medicine. On the one hand, because his patients so often need specialist help, and because contact with consultants and other colleagues is the best means of keeping medically alert and well informed, the practitioner should be much more closely associated with hospitals than is usual today. But, on the other hand, this association must not blind him to his own chief task, which is to look after people *outside* hospital—and keep them out of it when he properly can. Those practitioners who like to spend part of their time in hospital work should certainly do so, but it would be a great pity if many others did not prefer the work now done in public-health and school clinics, or take part in industrial medical services (though these, if Lord Taylor [36] has his way, will be under the wing of the hospital boards rather than of the local authorities).

Though, as already explained, I have lost faith in the kind of health centre we used to hope for, it did have the great merit of bringing the personal doctor into daily touch with people from the public-health department. The more closely they work together, the better for his patients.

SELECTION AND CONTINUING EDUCATION

The conclusion that henceforth we shall want personal doctors rather than general practitioners implies that many of our students ought to be selected for qualities other than (as Dr Lester Evans put it) being good at chemistry at school And whereas until recently our tendency on graduation day was to select the future specialists and let everybody else go into general practice, we might do better in future to select the future personal doctors and let everybody else be a specialist Besides techniques, the personal doctor should have character, much knowledge, many interests, and, above all, a capacity for identifying himself with his patient For, call it what you like, this is no easy role Silver[12] well summarises its exigent requirements when he asks

> "Who will see the patient in the first instance and determine if the complaint is minor or major? Who will refer cases to the specialists for more complex and precise diagnosis or treatment? Who will collate the reports as they come in? Who will adjust the *precise* 'scientific' reports or findings to the patient, that imprecise person of infinite variability? Who will be so intimately related to the family as to know the interpersonal problems, assess them in relationship to the complaints or symptoms, and provide the support and guidance that probably does more to determine the duration or severity of an illness than the specific treatment? Who will carry on the day-to-day psychosomatic practice? Who?"

One professor spoke for many when he said "Our educational system is producing experts, not doctors" But the doctor has to be an expert too

UNDERGRADUATE EDUCATION

What kind of training is required by the man who wants to be both?

Dr Proger says that in large towns the good family doctor is coming to be basically a well-trained internist[31] And this is in line with the North Carolina finding[33] that the longer a man's training in internal medicine, the more likely he was to be a good doctor

> "The importance of training in internal medicine lies not in the name of the discipline or service but rather in the comprehensive viewpoint and emphasis on the basic techniques of diagnosis These are the core of medical practice"

Comparing performance in the medical school with later performance in practice, the North Carolina investigators found evidence that a longer course in internal medicine makes up for lack of brilliance, turning some of the slower students into good physicians

Since most of us hold that all doctors—whatever they are to do later—require a sound general training, I let myself in for a snub from a Boston professor when I asked what kind of training he provided for personal care "Education", he replied, "should not be directed towards any special branch of medicine." But he agreed with me that it should not be directed *against* personal practice, as still too often happens In point of fact, his school and others in Boston use their home-care programme very skilfully to give students a view of the world outside hospital[37], and in New York Prof Duncan Clark[38] and Prof George Reader[39] told me about the ways in which their students make personal studies of families Apart from this, in many American medical schools the student is introduced to personal practice by preceptors—practitioners who either take students in the outpatient department or have them in their homes and practices during the vacations for anything up to several months

On the other hand, opinion is divided on the value of such schemes Some medical schools do not really want to send so many students to study with practitioners or in peripheral hospitals, but they have to do it because their own hospitals (perhaps in a smallish town) do not yield enough experience Though some preceptors are very good indeed, others are uninterested In support of his scheme by which practitioners have offices in the teaching hospital, Dr Proger's strongest argument, perhaps, is that "the student's familiarity with family medical practice becomes a part of his daily life"[31] it is an integral part of the curriculum—not something stuck on to it

POSTGRADUATE EDUCATION

But in medical education, Dr Hilleboe said, the main problem has now shifted from the student to the intern and resident, and to the practitioner with his need to keep up to date

Many American teachers feel that their medical schools must accept responsibility for the postgraduate, and they approve the idea by which university influence is supposed to permeate the National Health Service But attempts by universities to give leadership in their localities encounter obstacles within as well as without many of the staff, intent on research and teaching in their own departments, do not hold with universities assuming this external, social, role In the Middle West the valuable work of universities in raising standards of agriculture is said to have made them sometimes too utilitarian to use an ivory tower for silage can be a mistake in the long run Nevertheless, for medicine, I am on the side of those who think of the doctor as a perpetual student for whose continuing education the medical school should provide

The means whereby a university can spread knowledge and raise standards are the same in all countries It may have a say in the appointment of staff, both senior and junior, it may lay down conditions on which students will be sent to preceptors, or interns to hospitals, it may hold lectures or courses at the periphery, or it may persuade practitioners to come to courses at the centre

In courses at the periphery, I was told, practitioners are often reluctant to present cases and discuss them freely—fearing to lose face with their juniors or their fellows (Dr Rappleye thinks that, for this reason, an impersonal kind of teaching is best on the doctor's home ground) They are much more forthcoming, however, when brought to the centre

> Wisconsin University has a magnificent new postgraduate teaching centre, used by, among others, the agricultural and medical faculties, and here a recent course for pædiatric practitioners was made successful by splitting them into groups of six or eight, under a "tutor" Not knowing, or being in competition with, the other members of their group, they felt really free to talk—and did.

Except perhaps in Russia, the difficulty about central postgraduate courses is to get hold of the people who might profit most Though about 300 of Wisconsin's 3400 doctors attended one or more of the eleven courses last year, 100 were regular attenders and 50 almost addicts

But courses are not what matter most. The American Academy of General Practice insists on its members attending them Medical schools do well to spend time and trouble on making them both acceptable and valuable. And no doubt television will increase their range and

efficacy But, for the doctor as for the student, it remains true that the best way of learning is by *doing*

Dr Proger is right when he says that the best kind of postgraduate medical education is the kind that is a part of one's daily work Of the practitioners who have offices in his teaching hospital he wrote " One would not need to be concerned about courses for the family doctors who were a part of the center Their daily activities would constitute such a course, a continuing and permanent one "[31]

Though I should like to see his New England Medical Center experiment (and many others) tried in this country, I think it will end by orienting its doctors towards the hospital when they should be oriented towards the home For my part I believe that if the personal doctor is to exist at all, the centre of his work must be geographically as well as philosophically distant from the hospital But we cannot get away from the fact that the best—indeed the only—way of maintaining a reliable medical judgment is to be always discussing cases with hospital colleagues as well as fellow practitioners

Like the young man in *If* who was to walk with kings nor lose the common touch, the personal doctor must talk to specialists while preserving his own holism He may or not work part-time in the hospital, but he must be in and out of it Postgraduate courses are no substitute Even reading the journals, I fear, would not quite make up for lack of daily contact over patients

Medicine (as someone said to me) should always be practised in a critical environment

THE FUTURE

Both Dr Iago Galdston and Dr Lester Evans wisely tried to divert my thoughts from mechanisms to principles we should, they said, be worrying less about methods of *organising* care and more about the *kind* of care likely to be wanted in future

" Episodic " medicine in Galdston's view, is likely to decline (a new method of treating cancer might put most surgeons out of work), but " maintenance " medicine will still be needed Other authorities pointed out that against the growing complexity and scope of specialist work (e g , the extension of surgery if organ-grafting becomes feasible) must be set the simplification of many diagnostic and therapeutic tasks This may make it easy for practitioners to detect and manage diseases now requiring a lot of work in hospital "The Pap smear", Professor Rutstein remarked, " is more reliable than physical examination "

Also looking ahead, Dr Silver quoted A N Whitehead on the tendency of professional groups to take on new functions, deputing old ones to the group below Thus the nurse and social worker, following their upward course, can relieve the practitioner of much of his old work, leaving him free to specialise as an internist in a group

This is the argument behind Silver's experiments at the Montefiore Hospital, and it has far-reaching implications If we accept Whitehead's professional upgrading as a law of Nature, we must conclude that in the future very few doctors will want to do anything that could be done by an ancillary, and we must abandon the concept of a personal doctor who likes looking after people and is therefore content to do menial things for them as well as clever ones

But in a rational society natural processes would not necessarily continue unchecked, and we could decide that specialism in medicine is being carried too far If we liked, we could now close our ears to what this journal called the siren song of the specialist—*Anything you can do I can do better* For there is one very important thing that the specialist can seldom do as well—namely, look after people as people As Prof Nathan Smith said to me, " bringing specialist services to an area is one thing taking care of people is quite another "

Perhaps I am wrong, but I should guess that in the prevailing culture of the United States, the independent personal doctor is going to be specialised out of existence, and that within a few decades medical care will mostly be based on the hospitals Those who would like to keep the best of the old system cannot hope for much support from a public which has got rid of small shops in favour of supermarkets, and which so often actually prefers the mass-produced substitute to the genuine article One cannot rely on public instinct to choose the best, for in times of rapid change people often go astray over their real needs The American suburban woman with her car is probably gratified that she can now do her day's or week's shopping with hardly a human contact, but she was more likely to keep healthy and happy in the old days of walking and gossiping The up-to-date man or woman getting his medical care from an impersonal group instead of a personal doctor may unbeknown be losing even more

In the words of Lester Evans, whatever happens in medicine the age-old demand of the person—the patient —for help has to be satisfied, by somebody Somebody must listen to him if not the doctor, then the priest, or the social worker, or the osteopath In medical situations, the doctor is usually the helper to whom the patient turns first, and he therefore starts with a therapeutic advantage But he loses it if he sees his task as merely the recognition of primarily dangerous disease, if he fails to accept his patient as a person, or even if he asks somebody else to cope with the personal side In America I was told that people often favour small hospitals because they get T L C. This mysterious remedy turned out to be an old one— tender loving care Very often it is what they chiefly want from their own doctor

Much personal care can, as Professor Rutstein said, be given by the public-health nurse Which is true enough My point is that, unless the doctor gives it himself, no sufficient reason remains for his being an independent practitioner Sooner or later he must be absorbed by the hospital service

TWO KINDS OF DOCTOR ?

Though I think we should retain and strengthen the personal doctor as residuary legatee of the general practitioner, I know that this belief will seem to some both backward-looking and impracticable Dr Hilleboe, for example, found it hard to conceive of two separate kinds of doctor, and he thought that a man concentrating on personal care would inevitably have a lower professional status which would deter able students from such a career

If he meant that there should be one medical profession, not two, I am with him, and I would agree that in Britain the practitioner is already too far divided in practice from the specialist Nevertheless I think that a division of some sort is functionally correct because it corresponds to the patient's two needs—a primary need for personal care and a secondary need for specialist skills. Unless a division is preserved, the first of these needs will more and more go unfulfilled.

As for status, the personal doctor must make it very largely for himself. As the Royal Commission[40] has explained, in our changed society the doctor can very seldom enjoy the prestige that comes of being one of the few educated people in his neighbourhood, and nowadays his patients are less docile. Moreover, though the personal doctor should be paid as much as the average specialist, and exceptional performance (in this work as in the specialties) should be recognised financially and otherwise, he will seldom have a chance of the monetary and professional rewards that go to men who win a national or international reputation. He will have to be content with a small territory—often smaller than it is today—for nobody can give really personal care to a flock which is large or widely scattered. But think of the history of general practice, and its innumerable examples of a kind of prestige that the eminent consultant hardly ever gains. The deep regard of the people of a locality is at least as satisfying as the plaudits of a congress. And it takes at least as much earning.

Personal practice, admittedly, is scarcely worth attempting without a vocation for it. But possibly in future a growing proportion of the newly qualified will say "I'm going to be—not a radiologist, not a surgeon, not a biochemist—but a *doctor*." That, after all, was the thought with which many of them entered medicine. And a doctor is what 90% of the patients (though they may not know it) really need.

CONDITIONS FOR INDEPENDENT PRACTICE

But if we are making a serious attempt to develop good personal care in this country, good recruits are only a beginning. We must offer them conditions in which the odds are in favour of their improving steadily, as doctors, throughout their years in practice. At present the odds are often, if not usually, against.

To be a good personal doctor, a man must really take care of his patients: he must make diagnoses and take decisions—not merely write little notes to specialists. To shoulder such responsibility safely, he must know both his limitations and a great deal of medicine. And the best way of learning these, and keeping up to date, is frequent conversation with the specially informed.

In the National Health Service the financial incentives are mainly against the doctor who wants to look after a reasonable number of people and do all he can for them. If we mean to encourage such doctors, these incentives should be reviewed and probably revised. But, after my American visit, I have a new consciousness also of the harm done under our system by keeping practitioner and specialist so far apart. I remain convinced of the personal doctor's need for autonomy, but I now think this compatible with the kind of day-to-day contact at hospital which can make his own work so much more interesting and efficient.

The virtue of independence is nullified by isolation. The practitioner's usefulness and professional status depend on his being well informed, and in the modern world close association with the hospital is therefore a condition of his professional survival.

Some ways of strengthening that association have been suggested above, but there are others. Though we may not follow the Americans in everything, let us at least adopt—or rather resume—their excellent habit of wide experiment.

SUMMARY AND CONCLUSIONS

Except in isolated places, the general practitioner is already extinct.

In the Russian countryside, and in many American towns and villages, he has been replaced by a small group of doctors trained in different specialties—a "composite general practitioner."

But in Russian cities, and in some experimental American schemes, general practice as an independent activity disappears altogether. General medical care becomes one of the functions of a group which also gives specialist care.

Both in America and in Russia many such groups (clinics, policlinics, &c.) are still separate from hospitals. But the hospital is the natural centre for specialist work, and the groups will eventually be absorbed into the hospital organisation.

As medical centres for their area, the hospitals will then be offering full medical care. And if they do this satisfactorily there will be no place for the independent practitioner.

From the technical standpoint, this plan has obvious advantages. An internist, in easy consultation with other consultants and with beds at his disposal, can give the patient technically more than any independent practitioner. Hence the American public, already specialist-minded, may soon come to feel that hospital groups can best meet all its medical needs.

In our National Health Service such developments are impeded because the independent practitioner is protected, under an organisation separate from the hospitals. But his independence cannot be preserved indefinitely if his work could evidently be done better in a hospital milieu.

With the advance of specialisation, many of the functions of the independent practitioner have already been taken over by the hospital, and he will eventually be absorbed into the hospital system unless he is seen still to perform some important function for which independence is necessary.

The function which the good practitioner can in fact perform better than the best of hospital groups is personal medical care—looking after people as people. Whereas the specialist is, willy nilly, oriented towards the hospital, the independent doctor is well placed to think of people in their homes and workplaces, in health as well as in illness.

In these islands, with hospital specialists almost everywhere accessible, the general practitioner (composite or otherwise) is dead. But the personal doctor is needed more than ever.

Only if we clearly recognise his role can we set about fortifying him in it. To know what should be done for (and by) the independent practitioner, we must stop thinking about general practice and think instead about personal practice.

The change of name brings out better the importance of this part of medicine, for personal care is the primary medical need. But it also introduces a different criterion which displays different shortcomings and different ways of meeting them.

Looked at as "general", a practice may pass muster, or even appear good, if it ensures that serious illness is picked out and sent to hospital, but if we examine its merits as a "personal" practice it may be plainly on quite the wrong lines Thus in a general practice, as in a hospital, unhurried personal attention may seem no more than an amenity—something extra for which a charge might properly be made But in a personal practice it is the sine-qua-non

---

[40] Royal Commission on Doctors and Dentists' Remuneration, p. 106. H.M. Stationery Office, 1960.

Similarly some of the ways in which we have sought to improve general practice may be wrong if personal practice becomes our aim.

Personal medicine is practised by individuals, not by groups, so the personal doctor must look after people personally For treating people at home he should get whatever aid he needs from medical officer of health or hospital, but, though he must use ancillaries, the purpose of his existence may be defeated if he deputes too much work to other people

Similarly it may be defeated if, inspired by efficiency experts, he seems to put his patient on anything resembling a production line The hospital must be to some extent a factory, but the personal consulting-room must *not*

In the patient's eyes, the ideal doctor practises from his own house and is on duty twenty-four hours a day In real life the outside surgery or office, the partnership, and the duty roster are usually a necessity, but the surgery should be home-like and the partners preferably not more than one or two The large partnership tends to become a group with a clinic

The personal doctor who is keen on a specialty, or likes hospital practice, should have every chance to pursue it But while he is actually engaged in such work—which for him is a sideline—he cannot claim his usual autonomy He should do specialist work only as a member (internal or external) of a hospital department If they can accept this condition, a great many practitioners should go on doing obstetrics, both inside and outside hospital, and far more than at present should look after beds—especially in small hospitals and hospital annexes

Even if he holds no specialist appointment, the personal doctor should work as closely with hospitals and specialists as is possible without imperilling his independent and responsible status Those who are willing to help hospitals by supplying proper information about patients should be made associate members of the hospital staff, with appropriate privileges

To take care of patients as their personal doctor demands the continuous exercise of well-informed judgment, and for acquiring and maintaining such judgment no other form of postgraduate education can compare with frequent discussion of cases with colleagues

Personal medicine is a vocation, and it may or may not still attract enough people capable of taking its responsibilities But this much is clear Whether in America or here, the independent practitioner, outside hospital, will survive as a personal doctor—or not at all

Without specific action, it will be not at all

In the United States I was the guest of the Milbank Memorial Fund, whose president, Dr Frank G Boudreau, is the most perceptive of all hosts Some of the many other colleagues who helped me have been gratefully mentioned above, but I must particularly thank those who gave up whole days to my visit—notably Dr George Silver, Dr C B Esselstyn, Dr Joseph Garland, Dr Leslie Falk, Dr Thomas Nichols, Dr Henry T Clark, and Dr Nathan Smith—and also Dr O M Peterson for his advice on where I should go If those who entertained me should read this article, the thoughts of some of them may turn, I fear, to the Spartan boy who nourished a fox in his bosom But this fox at least recognises his good fortune

That I actually saw all the intended people (and one chipmunk) was through blindly following the detailed instructions of Miss Anne Donohue, *of the Milbank Memorial Fund*

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE completion of another stage in the buildings planned for the college in Lincoln's Inn Fields was celebrated on Tuesday when new laboratories were formally opened Guests were welcomed by the president, Sir James Paterson Ross, and heard about the rebuilding scheme from Sir Eric Riches, chairman of the building committee, and Mr Alner W Hall, the architect

The new floors which were opened this week lie behind the original college and adjoin the premises provided by phase I of the building programme (which included the Great Hall, museums, and laboratories) Phase II was the Nuffield College of Surgical Sciences, which stands on the east side of the college, and the buildings now completed and in use form phase IIIA The final phase, IIIB, now starting, will, by additions and alterations, accommodate departments of pharmacology and biochemistry and the Hunterian Museum

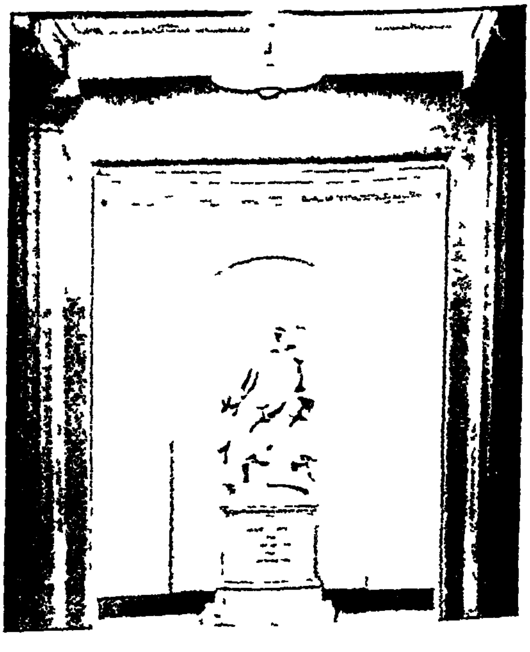
Phase IIIa

On the ground floor a skilfully lighted and comfortable lecture-room has been named after Sir Cuthbert Wallace, and next to it there are a committee-room, named after Mr W R Gibson, and a fellows' common-room, named after Sir John Bland-Sutton Where the new corridor joins that leading to the Great Hall, a rotunda has been created, in which stands Weekes' statue of John Hunter, which when the original college building is restored to normal will be visible from the front door

The first floor contains the department of dental science and the odontological museum, the only part of the college museum to escape the late war virtually undamaged

The second floor completes the suite of research laboratories for the department of pathology

The third floor includes the department of research in ophthalmology, formerly housed in one room in another part of the building With this department is the Wernher Group for Research in Ophthalmological Genetics (a unit of the Medical Research Council) A demonstration room on this



floor is shared by the departments of physiology and pharmacology

The fourth floor is for the department of anatomy and includes dissecting-room, demonstration room, and research laboratories The upper floors are known as the Simon Marks Laboratories

The College Appeal

The cost of completing the building programme is estimated at £350,000, and an additional annual income of £150,000 will be needed to support extensions of research and teaching Considerable funds were raised from a private appeal to friends of the college, which helped to complete phase IIIA, but it was necessary to broaden the appeal if these further commitments were to be met The college appeal committee, under the chairmanship of Lord Kindersley, launched this wide appeal, and a brochure describing the work of the college and the appeal may be had from the appeal secretary, Mr W F Davis

TRAINING OF NURSES

FOR some time the General Nursing Council have been concerned because some approved training-schools, where there is insufficient clinical experience, find it difficult to provide adequate training for their student nurses These hospitals often have difficulties in recruitment and tend to accept girls whose standard of education is inadequate This deteriorating situation can best be met, the Council believe, by reducing the number of training-schools and reintroducing a minimum educational standard of entry to training for student nurses

The Council have accordingly revised their conditions of approval of hospitals as training-schools for admission to the general part of the Register

A training-school may be made up of more than one hospital but it must have a minimum of 300 beds, with a daily average bed occupancy of not less than 240 beds The school must be able to offer varied clinical experience in different departments Special hospitals might thus suitably join general hospitals to form a training group, but the amalgamation of two or more small general hospitals to provide the minimum number of beds would not meet the new conditions of approval

The new conditions of approval will inevitably affect the status of smaller hospitals at present approved as complete training schools, but the Council believe that most of these will be able to join a group school for general training or become training-schools for assistant nurses The new conditions of approval will become effective at the beginning of 1964 for existing training-schools, new applications for approval would require to meet the new requirements

The condition of a minimum educational standard for entrants to training, which has been in abeyance since 1939, will be reintroduced in July, 1962 The Council were anxious that it should apply to training for all parts of the Register, but the Minister of Health has so far only given his approval for the parts for general, sick children's, and fever nurses At present he is not prepared to extend it to the parts for mental and mental-deficiency nurses

The entrance test set by the Council has been devised by the National Institute of Industrial Psychology and is already used by many training-schools on a voluntary basis It is in a form familiar to most schoolchildren, and it can be given and marked by training-school authorities at any convenient time Exemption from this test will be given to candidates who hold the General Certificate of Education at ordinary level in two subjects (one of which must be English or Welsh language) and who show evidence of a satisfactory standard in five other subjects

Though the annual intake of student nurses is 19,000 to 20,000, in a recent twelve-month period 8770 withdrew from training An "appreciable proportion" of this wastage lay among educationally unsuitable students Yet, as pupil assistant nurses, many might well have successfully completed their training and found the work interesting and satisfying The number of pupil assistant nurses is only now reaching 6000, and the Council believe that it would be more satisfactory for the future of nursing if it were increased by several thousands, even though this meant a reduction in the number of student nurses The title "assistant nurse" was sometimes said to be a deterrent to recruitment and the Council reaffirmed that they themselves would have no objection to the omission of the word "assistant", provided it was appreciated that this change did not imply a change in the conditions of training, and that the nurse would still work under the supervision of registered nurses or doctors

The Widdicombe File

LIX.—SO-CALLED COLLAGEN DISEASES

MY DEAR DAVEY,

You encouraged me to put on paper—rather more clearly, you said—the message I was uttering the other night between the chicken and that ghastly ice

I was talking about Klemperer and the group of diseases he has found himself fathering And I exploited this metaphor in a way that I thought you would appreciate But dinners are hopeless However, I have now elaborated it a bit

What I said was that it isn't always easy to see a likeness in the Klemperer family, and now and then he gives the impression of wanting to disown some of the progeny But we know he was around at the time, and even if he didn't really have any fixed intentions he certainly had a good idea It maybe wasn't a very clear idea, but it turned out to be a fertile one

Then he retired from the village for a bit, and to his surprise the brood were adopted wholesale by the Physicians Usually you pick an adoptee because you like the look of it, its baby eyes ask to be taken in to the comfort of your arms, and then you call it Rufus or some other pet name The Physicians didn't really look the brood in the eye, it wasn't the babes that were taken in, and the adoption, like most adoptions of Pathologists' babies by Physicians, happened because the babes had a euphonious name This is only so if the *g* is soft, and you'll find that the foster-parent Physicians show rapid and severe evidence of hypersensitivity if you refer to their precious bundles with a hard *g*

Nobody knows (I said) what would have happened to the little innocents if Dr K had pondered a day or two longer about their name before he slipped off on vacation If he had called them Collagenogenic, I'm willing to bet they would eventually have come under the institutional care of Pathologists Inc (of whom Dr K is an ornament), and that philanthropic body would have tutored them, done its best to encourage the development of character in each, and even perhaps have given each of them a significant name Pathologists Inc have been hesitant to offer their help to Dr K in view of this gratuitous adoption by the Physicians of his brood, another very massive reason for hesitation is the difficulty of amassing *facts* about a conception that was artistic (scientifically) and novel, rather than a mere utilitarian termination of a long argy-bargy

As a delicate first step to weaning the brood from their conservative fosterers, and perhaps reuniting them with Dr K, Pathologists Inc. should, I suggested, make a definite statement on such knowledge as they have about the Collagenogenic diseases And here is the test I now propose to you for discussion

This is a group of diseases of uncertain but possibly hyperergic origin, with focal lesions not always to be found by casual microscopists, these lesions being characterised by the escape from blood-vessels of substances that become deposited in or close to the vessels These substances are of different chemical characters and in their deposited state have received a set of humorous names—amyloid, fibrinoid, fibrin, red stuff (which is sometimes correct enough), and L E substance (which is reasonably non-committal)—and in some cases at least, if time permits, these substances become changed in time to a substance that looks and stains very like collagen

The correlation with the clinical picture, and suggested mechanisms for the toxic element, the anæmia, and the occasional response to steroid therapy may well be achieved once we have learnt to distinguish the brats from each other and to know which one we are talking about

I do hope you're sufficiently interested to do something Sorting out mixed-up families is the kind of thing Pathologists Inc is, or should be, for

Trusting the flame is lit,
Yours as ever,
J A

Conference

MENTAL HEALTH AT HOME AND ABROAD

THE annual conference of the National Association for Mental Health was held in London on March 24 and 25

Future Role of the Hospital

Dr H F OSMOND (Canada) described British and North American mental hospitals as generally grandiose, of weird design, costly to run, ill-equipped for their purpose, and without regard for human beings and human values A patient from a small prairie farm entered what appeared to be a Gothic castle, from whose entrance hall—high, gloomy, and dimly lit—long flights of stairs rose upwards into darkness The urge to impress had blotted out any other thought in the design of these buildings

The small hospital, advocated by Kirkbride in 1850, had been discarded in the search for economy, and a descending spiral of overcrowding and degradation had followed It was often said that mental hospitals should be home-like, but this implied that they were a permanent residence The scale of a building must be appropriate to its function, which in this case was to prepare patients for return to their own homes Without a clear idea of what the building was supposed to do, the architect could not plan a suitable structure Yet he was often prevented from meeting the medical and nursing staff, and the needs of its potential users tended to linger in the background

Hospital design must be related to our conceptions of the major mental illnesses—particularly schizophrenia, in which there appeared to be a disturbance of perceptual constancy With a surging mass of impressions, identity was difficult to determine and nothing was certainly familiar In such a case, there was no benefit to the patient from association with many people If, however, he could learn to deal with three or four, life outside was possible, and he should leave hospital, perhaps for lodgings, which Carstairs had shown to be often the most suitable environment The therapeutic-community principle overlooked the fact that reciprocal relationships were very rare among schizophrenics

Architects, psychologists, psychiatrists and others must study the needs of patients together, examining such questions as who talked to whom at tables, whether patients preferred an area of their own however small, and what unpleasant perceptual effects might result from building patterns or ambiguity in any situation

Dr E S STERN regarded mental hospitals as the appropriate centre for the psychiatric services of a district, but their situation must then be urban and not remote They should contain not more than 300 beds, in about twelve units

In the past century, huge hospitals had been built in the belief that patients could thereby be treated more cheaply The only meaningful cost was that per patient-illness, which, owing to the length of stay in most large hospitals, had made the intended economy in fact an extravagance

Sex separation, among patients and nursing staff, should be ended, and individual cooking on each ward should enable men and women to play their appropriate domestic roles To avoid family break-up, some or all of the close relatives might be admitted with the patient A special training unit, which was neither a factory nor a sheltered workshop, would be required for rehabilitation, and a proper library was essential for the educational function of the mental hospital At various stages of the illness, the environmental needs of patients varied, and, because of this, Dr Stern also called for cooperation between architects and medical staff Without it, any scheme would fail

On the basis of past experience, he doubted the value of a large permanent increase in psychiatric beds at general hospitals They tended to be in small units, hence there was a sense of hurry in treatment, and the transfer of long-stay patients meant that staff did not get a balanced view of psychiatric illness It was difficult to introduce a suitable attitude in hospitals constructed for the treatment of somatic disease, and he felt that the patient would do best to enter at the start a unit where there was no time-limit to treatment

Dr Stern's suggestion that the mental hospital should have accommodation for disturbed children and adolescents provoked comment on behalf both of pædiatric hospitals and of local authorities

As an architect, Prof LLEWELLYN DAVIES stated that the design of the older mental hospitals bore no relationship to the care of patients Those who had difficulty in relating space needed comprehensibility of layout around them Yet mental hospitals tended to show repetition of identical spaces and radiating passageways, which gave no sense of identity in space

Architects needed freedom to place the patient in different types of circumstances and to break down hospitals, but not into imitation private houses Groups of small rooms should be related around living areas, like a cluster of collegiate buildings, and great attention must be paid to colour and light Like Dr Osmond, he called for joint research projects so that architects could be trained who would have a shared understanding with doctors of what happened in hospitals

Community Care Services

Dr T A LAMBO (Nigeria) emphasised that in Africa everything is based on the family unity, and traditionally treatment is given in the home In Nigeria he had been provided with a hospital which no-one wanted to enter When the African patient was emotionally ill, the worst thing was to confront him with a new situation and new people

He had therefore extended the therapeutic activities to four surrounding villages, many of whose inhabitants found work at the hospital The villages had group activities such as dancing and story-telling, in which the patients joined All patients came with a relative (which the extended family system readily provided) and were then referred to the head of one of the villages, who accommodated them in a suitable household The relative accompanied the patient in all treatment activities, and, by caring for him made a large nursing staff unnecessary Since the patient was already living in a normal community, rehabilitation was not required

At first, patients had been very carefully selected, but all types were now dealt with except chronic degenerated schizophrenics These do not seem to occur in Africa, suggesting that chronicity was environmental rather than inherent in the illness

Dr **Alan Miller** (United States Public Health Service) emphasised the importance of further research to measure mental-health problems, their treatment, and the results Certification laws varied widely between the individual States and many were undergoing change In Idaho certification now involved responsibility for the care of the patient without the necessity for him to be admitted to an institution Community mental-health projects depended largely on local initiative with State and Federal assistance to varying extents

Dr D E **Cullington** suggested that our incomplete knowledge of the ætiology of mental illness did not mean that preventive measures were impossible, any more than they had been in the case of cholera Environmental stresses might be reduced if, for instance, health visitors emphasised the importance of love and security in infancy

In establishing hostels, local authorities should not make the same mistake as with mental hospitals, of creating large institutions In some cases it might be better not to have directly run hostels, but to board out patients in privately run homes

Caution in establishing hostels was also called for by Dr D H **Clark** We should have a definite idea of the reason why patients were going to them, and not decant large numbers of crippled people out of hospital merely for a change of custody As yet, the best provision for the mentally ill remained unknown

Medicine and the Law

Overriding the Parents

On Oct 27, 1959, a juvenile magistrates' court made an adoption order in respect of a six-year-old boy, though the child's mother had withdrawn her consent and the father, who was in prison, had returned a form from prison saying that he wished to oppose the adoption and to be heard in the matter The magistrates, in dispensing with the consent of both parents, apparently acted on no evidence, but only on a confidential report from the children's welfare officer The parents were never told how the case was put against them, the father was only told on the day after the hearing that the order had been made The father appealed

Mr Justice **Roxburgh** said that he must allow the appeal in order that the standards of British justice should appear to all the world to be maintained

The justices had made the order against the opposition of both parents, though the mother had vacillated throughout the proceedings for the painfully obvious reason that though she did not want to part with the child, she did not know how she could maintain him because of the low and intermittent earning capacity of the father

Magistrates must realise that their power to dispense with the consent of the parents on a set of proved facts did not mean that they could do so on material which was not in evidence behind the back of the person charged The purpose of the confidential reports in adoption cases was to satisfy magistrates that the adoption was for the benefit of the child, but this case showed how those reports could be abused The Adoption Act, 1958, provided that magistrates could dispense with consent of the parents to an order if they were satisfied on specific grounds That meant satisfied by evidence admissible in British courts of law, not upon secret reports

Even if the father had a poor record and had stolen a television set, that was no reason for depriving him of one of his children on the strength of a report he had never seen and which was not in evidence. The magistrates knew that the father wanted to oppose the application and also knew that the mother, who was unrepresented by any legal adviser, wanted to oppose it. Their minds were thoroughly poisoned against the father by this secret report Did his Lordship really have to tolerate a juvenile court condemning a man to lose his child on that sort of trial? The matter as regarded the mother was even worse. Not only was her consent never asked for, but she was before the magistrates opposing the application, and the grounds on which it was intended to deprive her of her child were never disclosed to her The case would be sent back for retrial by a differently constituted bench

The justices for the city of Liverpool refused to make an adoption order in respect of a boy aged 5

The parents had originally given their consent to the adoption but subsequently withdrew it. The father said that his wife threatened to leave him if he agreed to the adoption, and the wife said that she wanted the boy back and had been persuaded to agree, at first, by her husband. The justices said that, though they considered the boy would be better off with the adopters, they could not say that the parents were withholding their consent unreasonably or that they had failed to discharge their obligations as parents

The adopters appealed to the High Court and their appeal was dismissed

Mr Justice **Roxburgh** said that it was a serious thing to take away people's lawful children and it was not to be done by hole-and-corner methods The Adoption Act, 1958, did not allow it, nor would the moral sense of the community His Lordship could think of few penalties more serious for a father and mother who wanted to keep their child than to take it away from them without their consent He would have expected cases of that character to be conducted almost with the strictness of criminal trials

Though counsel for the adoptors realised that it was for them to prove that the parents' consent ought to be dispensed with, the justices' clerk apparently thought it was for the parents to justify their refusal After they had given evidence, when it was too late for them to defend themselves, the secret report of the children's welfare officer was read out. It was not on oath What could be more contrary to the principles of British justice than to read it out after they had given evidence? The adoptors gave no evidence and the justices, having retired, refused the adoption order

The justices undoubtedly came to the right conclusion, but for the wrong reasons They decided that the report showed no ground for dispensing with the parents' consent The reasons they gave for their decision made it plain that, had the report been strong enough, they would have been quite pleased to have dispensed with the parents' consent on the material in the report It was monstrous that these reports should be treated as evidence in a matter of this sort They were not on oath and related to matters which were not even within the knowledge of the person making them He would dismiss the appeal

Income-tax of Part-time Consultants

Five consultants carrying on private practice and also holding National Health Service part-time hospital appointments, who have been selected by the British Medical Association as "test cases" for the 4700 specialists in comparable circumstances, appealed against assessments to income-tax on their remuneration from their hospital appointments (including fees for domiciliary visits and locum tenens appointments) under schedule E They claimed that they should have been assessed in respect of such remuneration under schedule D

The Special Commissioners for Income Tax found that a hospital appointment was an "office" within schedule E, but that as such appointment was a necessary part of the exercise of the profession of consultant and merely incidental thereto, the remuneration for the hospital appointment should be assessed as part of the earnings of the consultants' profession under the more generous provisions of schedule D On appeal by the Crown, Mr Justice Upjohn [1] held in favour of the Crown that the appointments were public offices and that profits therefrom must be assessed under schedule E and the expenses thereof deducted under the rules applicable to that schedule, while the profits and expenses of the private practice must be dealt with separately under schedule D

The consultants appealed against this judgment and the Court of Appeal allowed the appeal

Lord EVERSHED, Master of the Rolls, said that the first question was whether the consultant should be assessed for income-tax on the profits from his private patients and from his appointment entirely under schedule D, or—as the Crown contended—under schedule D on his private practice and under schedule E on his emoluments from his hospital appointment

It was not disputed that all his profits from both sources arose from his one "job in life" as a consultant, and most people might ask "Why should it matter which?" The answer was that, despite the unity of the consultant's calling, the allowances and deductions which he could make under the two schedules differed, the standard of expenses being stricter under schedule E than under schedule D The answer to that first question depended on whether the part-time hospital appointment was an "office" within section 156(2) of the Income Tax Act 1952 In his Lordship's view it was, and domiciliary visits and locum tenens appointments were part of the duties of that "office"

It followed that the Crown was right on the first question, and that persons like these consultants must for tax purposes have one essential part of their single calling severed from the rest, have each item of their expenses similarly dissected, and apply a different justification to each dissected part That process was so artificial and formidable that it encouraged his Lordship to suggest that Parliament should now consider whether the distinction between the two schedules in the matter of deductions and allowances was justifiable

The second question was whether the sums which the consultant might deduct for his schedule D assessment were limited to sums wholly and exclusively expended for his private practice, or whether he might deduct all expenses incurred for the purpose of his single calling of consultant, even though such expenditure related to his hospital appointment and could not be allowed for the purposes of his schedule E assessment The answer turned on the word "profession" in section 137(*a*) of the Income Tax Act 1952, which the Crown said should be limited to that part of the profession relating to the private practice In his Lordship's view the language of that section did not admit of such limitation in a case where the Commissioners had found that the taxpayer's "job in life", namely, his profession, was the single profession of a consultant. If that was in truth his profession, then sums in fact wholly and exclusively expended for the purpose of that profession were deductible from his schedule-D assessment, and none the less so because they might have been attributable to his hospital appointment and would not be allowed under Schedule E. In the result the appeal must be allowed

Lord Justice PEARCE, concurring, said that in the frequent case where an "office" was found to be a necessary part of the exercise of a profession and merely incidental to it, there seemed to him nothing absurd in treating the expenses of that office as part of the expenses of the profession It was more reasonable than notionally dividing half a profession that had been found to be one entity, producing an artificial allocation of expenses between the two halves, and then allowing the expenses of one half and disallowing those of the other

Lord Justice HARMAN, also concurring, said that it was a notorious and long-standing injustice that the scale of allowances under schedule E were altogether more niggardly and restricted than those under schedule D Indeed, it had been said that the pleasure of life depended nowadays on the schedule under which a man lived The result in the present case could only follow in the special situation arising from the Commissioners' finding that only one profession was being followed, that the office was held merely as an incident of it, and that without it the whole profession could not in practice be carried on

Leave to appeal to the House of Lords was granted to the Crown

London Clinic's Appeal Successful

A private clinic sued the widow of a deceased patient for the balance of fees unpaid—£73—under a contract made with her to provide (inter alia) a skilled nursing service during her husband's stay in the clinic By her defence the widow set out numerous complaints as breaches of the clinic's duty under the contract, which breaches she alleged had shortened her husband's expectation of life, and she counterclaimed for damages based on those same allegations The trial judge dismissed her charges and counterclaim, and gave judgment for the clinic for the £73 claimed and costs The widow appealed in person to the Court of Appeal That court dismissed her appeal on her counterclaim but allowed her appeal on the clinic's claim [2] on the ground that the clinic had fallen short of the high standard required of an institution of its reputation and scale of charges (£5 5s basic charge per day) and they held that the widow need not pay any part of the £73

---

[1] *Lancet*, 1959, ii, 180

[2] *Ibid*, 1959, i, 1039

The court relied on three instances which they held to be shortcomings by the clinic relating to (i) a prescription wrongly entered on the patient's card, (ii) the failure of a nurse to check the nurses' report book against a doctor's prescription, and (iii) the provision of oxygen at the patient's bedside The widow was awarded the costs of that part of her appeal

The House of Lords allowed the clinic's appeal from those judgments, with costs

Lord RADCLIFFE said that in view of the line taken by the Court of Appeal it was important to recognise the issues raised at the trial The court had accepted the trial judge's finding that nothing done or omitted by the clinic had had any ill effect on the patient's physical condition, but they had held unanimously that the clinic could not recover any part of the outstanding balance of their charges They had regarded themselves as dealing with a case of set-off for damages arising from a partial breach of the undertaking to provide a skilled nursing service But that was not the set-off pleaded and it was difficult to see how, when there was no evidence, an appellate court could measure the value of the services actually given against the value of what the court regarded as the proper contractual standard

On the first supposed breach relating to the prescription his Lordship could not find any lack of skilled service nor did what had been done affect the patient in any way On the second, though the nursing staff might have been in error, there was an unbridgeable gap between one instance of carelessness by the nursing staff (which had no effect on the patient) and such failure in the general standard of nursing care owing under the contract as would justify disallowing by way of damages a sum equal to some 13 days of full daily charges On the third, the Court of Appeal seemed to think that the clinic was under a positive duty to have oxygen by the patient's bedside and to see that he got it whenever he was breathless, because that would have contributed to his comfort. Perhaps it would, but nothing in the evidence warranted saying that if oxygen was available outside a room and a patient had a bell, anything short of a high standard of nursing care was being shown.

The ground on which the widow's appeal had been allowed was not one which had been made an issue at the trial, and therefore to treat inadequacies of the nursing services as in themselves a breach of contract, even though no damage was caused to the patient's condition, was to make a new case for the widow She had had no counsel to represent her before the Court of Appeal and it was natural that that court had tried to guide her case into what seemed the most favourable channel But that course could not be taken without injustice to the clinic. The whole idea that one could treat continuous services such as had been supplied to the patient during five weeks as if they were goods or a commodity that had been sold, and so reduce the contract price by a set-off, was, to his Lordship a strange one.

As to "damages", even if his Lordship agreed with the Court of Appeal that there had been failure to observe an ascertainable standard of care, he would still not think that any consequences followed from them which could be called damages and set off against the fees contracted for When a body such as a nursing-home or a hotel undertook to provide accommodation and attention of however high or luxurious a standard, it did not warrant that its internal organisation for providing them would not at any time or in any particular be involved in a mistake or would at all times do everything in the best possible way So long as nothing was done or withheld that affected prejudicially the person to be served, he got what he, as the contracting party, stipulated for, and the defects, if such they were, in the internal organisation gave rise to no damages, because they did not touch him The appeal must be allowed with costs and the trial judge's judgment restored The situation was distressing and his Lordship regarded with dismay the position of the widow who must stand saddled with liability for a very heavy sum of costs She had maintained this litigation under the settled conviction that her husband's sad death was contributed to by the clinic The clinic, on the other hand, small as was the sum involved, had had to recognise that the charges she had made were highly prejudicial to their professional status and the skill and competence of their nursing staff They could not be blamed if they had carried the adverse judgment of the Court of Appeal to the highest court The other members of the House concurred

Parliament

QUESTION TIME

Strontium 90 in Bones of Children

Mr FRANK ALLAUN asked the Minister of Health if he would make a statement on the latest Harwell report showing the approximate doubling, within six months, of the strontium 90 found in British children's bones —Mr DEREK WALKER-SMITH replied that the increases reflected the increased rate of fallout deposition in the six months following heavy nuclear weapon testing in northern latitudes in 1958 There had been no test explosions other than the recent French test since November, 1958, and levels of fallout in this country had fallen substantially since June, 1959 The Medical Research Council had kept the matter under constant review and was preparing a further report.

Mr ALLAUN Is not the increase likely to continue, particularly in children born after June, 1959? Secondly, is it possible that some scientists may be mistaken about the safe level or the danger level just as they were about X rays?—Mr WALKER-SMITH Provided that no further quantities are injected into the stratosphere, it is unlikely that the level of strontium 90 in children's bones will rise much above its present level, and subsequently it will probably fall The reply to the second part of the question is "No"—no mistake. This is a field in which knowledge is fast developing, and, therefore, we look forward to a new assessment by the Medical Research Council

The French Bomb

Mr WALKER-SMITH said that fission products believed to be due to the French atomic explosion were detected in air in the United Kingdom in the period Feb 27 to March 1 and in rain on Feb 29 The total radioactivity from fission products during this period of four days reached about twice that still being recorded from earlier nuclear explosions but was less than 1% of the normal amount of natural radioactivity in air The total radioactivity from fission products in rain on Feb 29 was about twice that from fission products present on the average from earlier nuclear tests, but less than a tenth of the total a year ago The small increase in radioactivity over this short period was due mostly to short-lived radioactivity, and only very small amounts of the long-lived isotopes, such as strontium 90 and cæsium 137 were present

Overriding the Parents

Dr DONALD JOHNSON asked the Minister whether, in view of the breach of the long-established precedent that parents should be responsible for their children in all decisions concerning medical treatment which was involved in the action of the Sheffield Regional Board in establishing special juvenile courts in hospitals with powers to transfer responsibility to local authorities if parents refused permission for an operation on a child, he would request the board to postpone invitations to magistrates to set up such courts until the matter had been discussed on a national basis, and whether he would issue a whitepaper with a view to promoting such discussion —Mr WALKER-SMITH replied Whether the provisions of the Children and Young Persons Act, 1933, would apply to a case of this kind, and what would be the effect of any order made under them, are questions of law on which it would not be appropriate for me to express any opinion Accordingly, I would not feel justified in intervening, and see no reason to issue a whitepaper on the subject

Dr JOHNSON May I ask my right hon and learned Friend, however, what advice he has given to this regional hospital board in regard to section 102 (1) of this Act, whereby parents are allowed an appeal to quarter sessions in a case such as this, and whether or not, in his opinion, that does not completely invalidate the procedure the board project in these circumstances, and, accordingly, indicate that fresh amending legislation, or legislation, is necessary for anything of this nature ?—Mr WALKER-SMITH No I am sure that the regional hospital board is aware of the provisions of section 102 in regard to appeals The regional hospital board is not seeking the use of any new powers in this context but merely trying to ensure that where the existing procedure is applicable it should operate speedily

W H O Malaria Eradication Fund

Mr L A PAVITT asked the Minister what reply was given by Her Majesty's Government to the request of the World Health Organisation for a contribution to its special malaria eradication fund —Mr WALKER-SMITH replied H M Government regretted that they did not feel able to make any further contribution to malaria eradication work additional to that which they already make by way of their contributions to the regular budgets of the World Health Organisation and to the United Nations Children's Fund and the Expanded Programme of Technical Assistance, as well as by way of the antimalaria work undertaken in Her Majesty's territories overseas Mr PAVITT Whilst appreciating the Minister's regret, in view of the fact that there are some 250 million potential victims of malaria, will he think further on the question of responding to this special appeal ?—Mr WALKER-SMITH We do not think that voluntary special ad-hoc funds are a sound way of financing continuing programmes of international organisations which have a regular budget We feel that such activities should be part of a coordinated programme within a regular budget drawn up with predetermined priorities

Care of Children's Teeth

On March 24, in the House of Lords, Lord TEVIOT asked H M Government whether, in view of the unsatisfactory condition of our children's teeth, they would consider favourably supplying without charge a mug and toothbrush to all national schoolchildren —Lord ST OSWALD replied The proposal seems to imply that the provision of Government toothbrushes and Government toothmugs would produce a dramatic improvement in the teeth of the children of this country and that the unsatisfactory state of children's teeth today is mainly caused by their failure to use these implements Neither of these premises stands up to serious examination The chief cause of dental decay in children is the large quantities of sweets and biscuits munched between meals Moreover the provision of mugs and toothbrushes would have little purpose without supervision of their use, and this would inflict a serious problem of organisation upon teachers which the Government do not think they should, or should be asked to, undertake Both the provision of equipment and supervision of its use is more properly, more conveniently, and more effectively left as a parental responsibility The whole problem of the care of teeth is under review by the Standing Advisory Committee on Dental Health Education, and the Government would prefer to await any recommendations by that committee before coming to any decision

In England Now

A Running Commentary by Peripatetic Correspondents

IN interviewing a succession of dailies over the past twelve years—put together they would make a good-sized Monday morning surgery—I have noticed a commonly recurring factor either they were already on my husband's list and declared undying faith, or oddly enough they were just about to " change doctors "

The reason for changing doctors was often given before the reasons for changing employment, and I was regaled with indignant talk of how " He only just looked at me—didn't even examine me " Too inveterate an employer to be thus decoyed, and metaphorically feeling my husband's steely eye (not to mention the G M C 's collective organ) fixed upon me, I hastily parry this with "But, ah, doctors *know* The sixth sense, and all that!" Or, if the daily is actually upright, on two feet, and appears at all sound in mind, sight, and hearing (I have had all kinds) I refer happily to her obvious robust health, and if necessary that of her attendant offspring, as a tribute and monument to her ex-doctor's skill and care

But in quieter moments I have reflected on this, and the patient in me rears its ugly head Perhaps one could expect a little examination—just a very short one Of course I know all about clinical intuition and skill, years of practice, and so on, but after years of cake-making, I still prefer to use the scales or a well-tried spoon

In my youth there was a strict, but much loved, family doctor, both wily and wise, who had a wonderfully brief but effective technique Whatever the complaint he would smartly pull down the lower lid and give a penetrating scowl at the conjunctiva Poets have written of eyes speaking volumes Those eyes were a complete encyclopædia of diagnosis The beauty of this simple technique was in its speed, absence of instruments, and satisfying mystique I have heard his patients say " He just looked into my eyes and pulled down the lid and he could tell at once " This, usually accompanied by some illustrative action which could be witnessed by a sympathetic audience, was most effective The resultant sputnik-like orb, with a gory or fish-like crescent beneath, always convinced sceptics that So-and-So had had a fair hearing

It might even have actually indicated something

There are fewer cleaners among our patients now Not because we now deal with a higher social strata There are just fewer cleaners

* * *

Someone had been to see a film about lemmings, those odd Scandinavian rodents which at irregular intervals proceed in countless numbers along a straight line until they reach the North Sea into which they plunge and are drowned We asked the reason why There are, it seems, several rather shaky schools of thought One maintains that the lemmings' built-in migratory compasses are off the beam, another, sponsored by the *Encyclopædia Britannica*, holds that the lemming is a slave to habits acquired when the North Sea was dry land, and a third that they are used to swimming rivers and mistake the sea for one This was too much for the departmental cynic " The one-more-river-to-cross school, I suppose," he said. " If you ask me," he added, " the answer's a lemming "

* * *

I seem to have an extraordinary capacity for doing things at exactly the wrong time Like exams, for example No sooner have I passed the thing than the examining board feel there's no point in holding it any longer and *abolish* it, as they did the London M D part I after I had passed with much trouble and expense I'd meant to take it a year or two before, and, had I done so, I would now probably be a real proper doctor, but as it is, what with the thesis they've started now, I'm back to square 1 On the occasions when they haven't abolished the exam on my behalf, they've raised the fees as soon as my name is noted in the list of candidates The worst example of such victimisation was the time they put the registration fee up from 3 guineas, was it, to about 11!

I'm no luckier with my science. No sooner do I thoroughly master some technique than it goes out of fashion. Like pneumothorax. I spent long hours pumping air in and sucking it out with those little machines that pop up and down or else with those great big ones that leak dirty water. Now I can't any more. Drugs go off the market as soon as I've learnt the dose—apart from digitalis which seems about the only one to accompany me faithfully on the road of clinical progress. Changing, in despair, to psychiatry from medicine I find myself even more at the mercy of the veering winds of fashion. I learned all about insulin coma just before it died, and I seriously wonder, with all these new drugs about, how long I shall be giving E.C.T.

Still, maybe someday they will all come back and my long-lost skill will place me at forefront. And I must say that whoever is Behind it All has not acted entirely with malevolence. I just got in before that confounded preregistration year.

* * *

The man in dungarees who entered the casualty department was asked why he had come. "I've got the gravel," he replied. He was asked to wait behind the screen in a cubicle. Five minutes later a casualty dresser went in to get the history. "What is this you were saying about gravel?" "It's in my lorry outside. Where am I supposed to put it?"

* * *

"Why are all those people called patients, daddy?"

"Er, well I don't know really."

"Mummy says it's because they have to wait out there so long."

"Oh."

"What's G.P. mean?"

"General practitioner."

"What's that?"

"Well, someone who practises medicine."

"How long have you been practising, daddy?"

"Oh, about five years now."

"I suppose when you start doing it properly they won't be patients any more."

* * *

The fracture clinic was grinding its way steadily through the waiting patients, with every chair and bench occupied. A figure strolling along the corridor to the X-ray department was vaguely recognised by one of the staff, partly by the arm which he had slung under his sweater. "Have you been sent back for another film?" asked the radiographer. "No," replied the patient. "How long have you been waiting since you were X-rayed?" was the next question, to which the patient replied "Nearly a day. I'm hoping to be able to find somewhere to sit down."

* * *

The Paranoid's Prayer—Lord, let what I think be what I think I think.

SPRINGTIME SAPPHIC

Twenty years have flown since the swallows nesting
High on stable beam in the April sunshine,
Fought and won the right to inherit next year
Back in our homeland.

Twenty years have flown since the Spitfires curving
High in Kentish skies for the same brave question,
Who shall fly on? Who to the garden diving?
Back in our homeland.

Twenty years now gleam on the rockets pointing
High in English skies, with their radar pulses
Questing still for hope of a peaceful echo
Back in our homeland.

Letters to the Editor

CHILDREN IN POINTED SHOES

SIR,—The matter of foot defects in children caused by unsuitable footwear was the subject of a question in the House of Commons on Feb. 1, and it has been discussed in medical journals[1-3] recently.

It seems to me fundamental in such a discussion to distinguish between abnormalities of the structure of the foot and disorders of the function of the foot (whether or not associated with deformity). One must decide to what extent abnormalities of structure (e.g., hallux valgus) are attributable to the external pressure of an unsuitable shoe, to what extent unsuitable shoes produce disorders of function, and to what extent, if any, disorders of function may cause abnormalities of the structure of the growing foot.

If hallux valgus is due merely to the intermittent external pressure of a shoe why do we find the regular wearing of a "hallux-valgus night-splint" so ineffective in reversing the deformity even when well-designed shoes are worn, why is the deformity sometimes entirely unilateral, why does the incidence of hallux valgus begin to increase with age more rapidly in girls than in boys even before the age of nine years (i.e., at a period of life when girls and boys wear similar shoes), why does it occur at all—however seldom—in people who never wear shoes?

If there is a poor case for insisting that hallux valgus is produced by the intermittent external pressure of a pointed shoe there is a good case for stating that unsuitable footwear, by restricting the normal movements of the foot, is a source of disability. If we consider only the adolescent female it is the "casual" rather than the shoe with the high heel and pointed toe which is a common source of trouble. A normal heel-toe gait is hardly possible in a loose-fitting "casual" and it is certainly impossible to run properly when wearing such shoes. This type of footwear is kept on by clawing the toes and by a shuffling gait. The foot does not function properly and symptoms of foot strain develop. In clinical work one commonly sees adolescent females with such symptoms attributable to such a source.

To what extent disorders of function can lead to deformities of the foot is a difficult problem worth more consideration. In this regard it is worth mentioning some results of a comparison of foot forms among the non-shoe-wearing and shoe-wearing Chinese population of Hong Kong.[4]

This survey showed a 33% incidence of hallux valgus among the shod as compared with a 1·9% incidence among the unshod. It also showed, however, that metatarsus atavicus, metatarsus latus, metatarsus primus varus, and hypermobility of the metatarsus all occurred much more frequently among the unshod, the figures being respectively 16·8 7, 38·3 7, 24·3 6, 13·1 0·9. Now, the unshod were chosen entirely from the fishing population who live aboard their boats and who use the hallux and forefoot to hold fishing nets and lines taut. It seems evident that the high incidence of splaying and hypermobility of the metatarsus in these people is an expression of function. Is the low incidence of hallux valgus among the unshod not, therefore, an expression of function and the high incidence of this condition among the shod a sequel of dysfunction and not a product merely of external pressure? (To judge from photographs of them, some of the shoes worn did not in fact exert pressure on the hallux.)

The point I wish to emphasise is that if our criticism of children's footwear is to be heeded it must be made for the right reasons. There is an arguable case for insisting

on better designs of footwear to allow children's feet to function properly but to insist that shoes merely by external pressure produce deformities is not a sound argument

Lincoln DAVID F THOMAS

SIR,—Many of my friends, both male and female, wear and are proud of shoes that bear no resemblance whatever in shape to the feet inside them Do these shoes not have an effect upon the feet that wear them?

My recent experience of nursing in a mental hospital would lead me to believe that much of the old patients' foot troubles are due to a long term of cobbling on " shoe strings ", with footwear that fits where it touches

London, W 5 KAY MOTTRAM

FLUORIDATION AND GASTRIC CANCER

SIR,—As no figures are given it is not possible to say whether the disparity noted by Dr Burrowes (March 26) between the mortality for gastric cancer in two small Lincolnshire towns might have arisen as the result of a chance fluctuation affecting populations of this size Assuming, however, that this difference is a " real " one, available evidence would not support the suggestion that the difference could be related to the difference in the fluoride content of the water-supplies concerned

The highest mortality-rates from gastric cancer in this country are to be found in North and West Wales where, so far as I know, *no water-supply has ever been reported as containing* more than a trace of fluoride West Hartlepools and South Shields have both had in the past appreciable amounts of fluoride in their supplies (approximately 2 5 and 1 4 p p m respectively) Both are county boroughs The data on which the following table is based can be extracted from the area mortality report of the 1951 census [1] Two neighbouring county boroughs on the North-East coast (Sunderland and Tynemouth) with fluoride-free water-supplies have been chosen for comparison The standardised mortality-rate (S M R) is the ratio (expressed as a percentage) of the number of deaths observed in the area to the number that would be expected to occur if the age-specific mortality-rates for England and Wales had applied to the local population The standard error of the S M R may be taken as the S M R divided by the square root of the number of deaths involved The period covered is the four years 1950–53

Gastric Cancer S.M.R
(England and Wales = 100)

	Male	*Female*	*Both sexes*
South Shields	145 ± 16 9	159 ± 21·6	151 ± 13 3

Fluoride areas	138 ± 12 5	141 ± 13 4	139 ± 9 6
Non-fluoride areas	149 ± 11 5	135 ± 12 1	143 ± 8 4

All four county boroughs have higher than average mortalities when compared with England and Wales, but there is nothing in these figures to suggest that the area mortalities differ significantly among themselves with respect to the fluoride content of their water-supplies

Curious local differences in the mortality from gastric cancer similar to that noted by Dr Burrowes have been observed elsewhere in this country and in Holland [2] Stocks and Davies [3] have recently been investigating an almost comparable situation affecting two neighbouring towns in Devon It seems likely that such differences may turn out to be related to differences in either the trace-element content or the organic content of local soils [4]

Anglesey G WYNNE GRIFFITH

FLUORIDATION

SIR,—Though I was glad to see your survey of the fluoridation position I was sorry to find that it restricted itself to one minor aspect of this much vexed question—dental caries in children It is evident that the point of my letter in *The Sunday Times* [5] was misunderstood My intention was to refer, not to an " optimum fluoride level of 1 2 p p m for caries control ", but to levels of 2 p p m upwards, at which the graphs both of Dean [6] and Forrest [7] show the caries experience at a minimum The minimum for Forrest's graph is shown actually at 3 5 p p m at which level objectionable fluorosis would certainly occur It follows that the levels of 1 or 1 2 p p m commonly referred to as " optimal " for caries control are in fact " maximal " for the avoidance of a toxic symptom, and even so, it is not possible completely to separate any useful degree of caries control by fluoride in the drinking water from some degree of mottling, however mild at the lower levels

The point is made, not in connection with teeth, but to contest the impression which is being given to the public by medical officers and others, that fluorides, though admittedly poisonous in big doses, change their nature at the low levels contemplated for fluoridation, and become " beneficial " substances, sometimes even stated to be essential nutrients for the living cell This is quite unjustifiable The only proven effect which may be called " beneficial " is that upon a non-living material, the dental enamel When this is obtained by topical application I understand that no mottling occurs even with a 2% solution When it is obtained by drinking the water it is accompanied by some degree of dental fluorosis, which has hitherto been accepted as the most sensitive sign of chronic low-grade poisoning (e g , see Hodge and Smith [8]) This provides no basis at all for risking the health of large numbers of people on a mere speculation that there is a critical level below which the fluoride ion loses its toxic character and becomes physiologically beneficial When, further, we learn from such a high authority as Prof Hugo Theorell [9] that, far from losing its activity as an enzyme-inhibitor at low levels, the fluoride ion can inhibit lipase at 1 part in 5 million, it becomes most extraordinary that the fluoridation discussion should always centre on the dental caries aspect rather than on the desirability of increasing permanently the general intake of a substance having these biochemical properties

Fluorides are common, toxic pollutants of air, water, and vegetation The eighth symposium of the Institute of Biology, recently published,[10] deals with the effects of pollution on living material, and confirms the view that the effects of toxic pollution become recognisable only at high levels, when such crude phenomena as wholesale destruction of fish, crippling fluorosis in cattle, radiation sickness, or the deaths of thousands of Londoners during the 1952 smog, draw attention to the dangers At lower levels there can be no direct evidence unless experimentation is carried out on an impossibly massive scale In the absence of such experimentation there must remain a strong presumption in favour of reducing, and above all against deliberately raising, the level of pollution with any toxic substance, especially in an essential of life such as the drinking water of large populations In the case of fluoride the circumstantial evidence that it remains potentially toxic at very low levels is even stronger than with other dangerous pollutants such as radioactive substances

[10] Symposia of the Institute of Biology, no 8 Edited by W B Yapp London, 1959

Your survey ends with the view that it is clinical judgment that counts, but here I must beg to differ By abandoning individual treatment in which they are trained, and launching themselves into the mass-dosing of large populations—a field familiar enough to the plant and animal pathologist, but, I submit, entirely new to the experience, as well as the ethics, of medicine—the medical and dental professions are abandoning also the clinical basis of judgment, and committing themselves to statistics Obviously, the larger the population subjected to treatment, the more is this true, and the less significance can be attached to the necessarily limited numbers of individuals who can be clinically examined with a view to the particular hazard in question

I have drawn attention elsewhere[11] to the gross statistical inadequacy of the evidence adduced for the harmlessness of fluorides at fluoridation levels, which is far less adequate even than that adduced for their effectiveness in caries control, but the point has been evaded There seems to be little realisation among those who favour this measure that the numerical relationships involved in population-treatment are widely different from those involved in the ordinary practice of medicine or dentistry where risks of the order of 1 in 10,000 or 100,000 need scarcely be considered when a highly probable benefit is in prospect. Yet to impose such risks upon the entire population of a large town, let alone a nation, would be almost certainly to inflict injury or death of a statistical order comparable to that inflicted, for instance, by poliomyelitis, with the difference, however, that the effect would be obscured by the multiplicity of other causes operating, and unlikely to be detected either clinically or statistically

Surely such a risk cannot be imposed on a basis of mere speculative opinion! The very least that critics of fluoridation are entitled to is an accurate estimate of the lowest significant differences both in mortality and morbidity which can be shown by the evidence which is alleged to show the harmlessness of fluoridation, and, above all, an open and unprejudiced discussion of this important aspect of the matter

The publication of Sutton's criticisms of the fluoridation trials[12] has, at last, resulted in some discussion of their shortcomings, but this makes it all the more disturbing that the various committees and professional bodies which have considered and published reports favourable to fluoridation have either failed to perceive, or else chosen to suppress any mention of, these quite obvious and elementary grounds for criticism. In the same way it has been left to me[11 13] to draw attention to the ludicrous inadequacy of the Bartlett-Cameron study[14] as a basis for assurances of "safety", and since my intervention a committee reporting to the American Medical Association[15] has shown that the mortality in the sample from Bartlett was, even after age-correction, significantly greater than that in the control sample, yet this study is still doggedly quoted to the public as evidence of "safety", and there has been no acknowledgment of the point, or defence offered, or intelligent discussion of the matter

Under the circumstances it is not surprising that a great many people are convinced that they are being made the victims of mere prejudice arising from intensive propaganda and activity by the promotionists, and are likely to remain of that opinion until the more obvious and valid criticisms which can be brought against fluoridation are authoritatively presented and fully discussed, as has occurred in other countries such as Sweden and France, rather than being, as at present, left to the responsibility of random members of the public

MATERNITY HOSPITAL REPORTS

SIR,—The long hours spent by junior medical staff in preparing these reports can only be justified if they are studied and discussed by all members of the obstetric staff of the unit concerned within a month or two of the end of the year to which they refer This is a far more useful pastime than the widespread distribution of detailed reports several years out of date

It may be true, as your annotation of March 19 says, that the considerable mortality and morbidity associated with childbirth is no longer a feature of the maternity report, but there are few obstetric units which can honestly contemplate with complete equanimity their last year's report Careful study will almost invariably reveal that some aspect of the work of the unit needs improving Herein lies the real value of the maternity report in providing not only a means of comparison of results with generally acceptable standards but also a way of gauging progress from year to year Unfortunately, medical, administrative, and printing delays often combine to reduce the report to the status of a belated symbol of local prestige destined to adorn countless bookshelves up and down the country, unloved by those who have to finance their production and unread by those for whom the reading would be the most instructive

London, S E 3
J M BRUDENELL

BRETYLIUM TOSYLATE IN THE TREATMENT OF HYPERTENSION

SIR,—Dr Lowe and Professor Rosenheim (March 19) have drawn attention to an important side-effect of bretylium which, in our experience, is potentially dangerous Syncope may occur suddenly and unpredictably on mild or brief exercise such as a short period of hurry, not necessarily running, for a bus In two of our patients this has nearly increased the toll of deaths on the road and in others of accidents in the home

Syncope may also occur apart from exertion One of our patients has twice fainted whilst sitting in a chair but curiously enough postural hypotension with resultant syncope seems to be less frequent than with ganglion-blocking drugs In every case so far syncope has occurred in patients in whom the standing diastolic pressure, when last recorded in the clinic, was still high

As regards dyspnœa it is difficult to see how a fall of blood-pressure could itself result in this symptom and there is good reason to believe that a hæmodynamic explanation will be forthcoming in the near future Likewise there is likely to be a full explanation for syncope on exertion

Dizziness, which in our experience is a common complaint, may occur whilst merely strolling in the ward or working in the home or even at rest—again in patients without demonstrable postural hypotension Until we recognised its significance this symptom was in some patients attributed to neurosis In fact, we were inclined in the early days to attribute a number of side-effects to neurosis until it was apparent that they fell into clearly defined patterns

From the pharmacological point of view bretylium is a fascinating drug and its many bizarre effects are providing a great stimulus to research

Treatment, however, is beset with difficulties not only from tolerance, variable response, and side-effects but also because it seems likely that some patients with severe hypertension have already lost their lives from persevering too long with bretylium when the pressure could probably have been better controlled with more conventional treatment Meanwhile it is most important that all physicians and practitioners should be aware that bretylium, for all its advantages, is a difficult drug to *manage and potentially the most dangerous preparation in* current use for the treatment of hypertension so that it must be given only with great care and under close supervision We ourselves look forward to its successor

"LIES, DAMNED LIES, AND STATISTICS"

SIR,—Dr Stoddart, in his letter of March 19, is, after all, saying only that figures lie when liars figure—a truth long recognised by professional statisticians who, more than any, deplore "woolly thinking on the question of statistics" But Dr Stoddart is being too hard on his own profession The standard of statistical analysis in the medical Press has improved enormously in the last decade or so, and it is still improving

London, W 1 BERNARD BENJAMIN

ROLE OF FUNDUS IN PREVENTION OF GASTRO-ŒSOPHAGEAL REGURGITATION

SIR,—Mr Goldberg (March 19) states that the sphincteric function of the lower œsophagus fails when the cardia is situated above the diaphragm and that this failure cannot be explained

The presence in the lowermost œsophagus of a zone that acts as a physiological sphincter is well established It is based on the manometric studies of Fyke et al , and of others who found a band of elevated resting pressure which extends from 1–2 cm below the diaphragm to 1–2 cm above the diaphragmatic hiatus The pressure in this zone is such that in both phases of respiration a barrier of high pressure exists between the stomach and the œsophagus At the end of expiration the band of high pressure lies mainly above the diaphragmatic hiatus, whereas at the end of inspiration it is wholly below the diaphragm At the end of inspiration only the infradiaphragmatic part of the gastro-œsophageal sphincter constitutes a barrier against gastro-œsophageal reflux It should be emphasised that it is *not an anatomical segment of the œsophagus that moves downwards with inspiration and upwards with expiration*, it is only a shift in maximal pressure from the superior to the inferior part of the sphincteric zone and vice versa This shift of maximal pressure, which is so important for the normal function of the closing mechanism of the cardia, is made possible by the fact that part of the sphincteric zone is situated in the abdominal cavity Indeed, the intraluminal pressure in *the sphincteric segment is the result of two forces—namely*, the muscular tone of this segment and the influence of extra-œsophageal respiratory pressure variations in the thorax and the abdomen With inspiration the intrathoracic pressure decreases and the intra-abdominal pressure increases, thus resulting in a decrease of the intraluminal pressure in the supradiaphragmatic segment of the physiological sphincter and an increase of pressure in the infradiaphragmatic part of the sphincteric segment *For this reason the band of high pressure,* and consequently the barrier against gastro-œsophageal reflux, is wholly below the diaphragm at the end of inspiration

In the presence of a sliding hiatus hernia the entire sphincteric segment is situated in the thoracic cavity Inspiration decreases the pressure of the entire zone When, in these circumstances, the tone of the sphincteric segment *is not strong enough*, inspiration results in an abolishment of the barrier against reflux *This is one of the reasons* why the sphincteric mechanism may fail when the cardia is situated above the diaphragm

We should like to ask Mr Goldberg whether suturing the fundus of the stomach to the lower end of the œsophagus in cases of hiatus hernia, "restoring as perfectly as possible th *normal anatomical appearances of the cardiac and fundal region*", did not result in the downward displacement and the re-creation of an intra-abdominal part of the physiologic sphincter

PEPTIC ULCER IN TOWN AND COUNTRY

SIR,—In your leading article of Feb 27 you draw attention to the careful survey carried out by Pulvertaft of the incidence of *proven* new cases of duodenal and gastric ulcer in York and its environs You justifiably emphasise the *importance of the stringent criteria* of diagnosis adopted by Pulvertaft to ensure the comparability of his cases

We wish to draw your readers' attention to a possible disadvantage of data based on such stringent criteria There is the danger that in interpreting regional and other variations in these confirmed cases of peptic ulcer it may be implicitly, and possibly falsely, assumed that the number of persons with a newly proven ulcer (involving hospital diagnosis) will be directly related to the number of persons at the pre-ulcer stage of the disease

Patients whose clinical condition satisfies the strict standards adopted by Pulvertaft will have already reached the established ulcer stage of a disease which, as we have shown,[1] may have a milder pre-ulcerous stage That such a pre-ulcerous stage exists is implicitly acknowledged by Pulvertaft and other workers, in their assessment of the age at onset when the first symptoms appear In the paper referred to above, we reported that of the 25 patients with "? peptic ulcer" non *ulcer dyspepsia, 6 had passed into the proven* ulcer category (on Pulvertaft's criteria) during a period of approximately eighteen months

In this connection it is of interest to note that the shape of Pulvertaft's graph showing the incidence of new peptic-ulcer cases according to age at onset among males is similar to that of our graph of the prevalence of non-ulcer dyspepsia for old and new cases Both graphs show a tendency to two peaks, one between the ages of 25 and 35 years, the other at 65 years, although the double peak is not so marked in Pulvertaft's graph A similarity can also be found between our graph of peptic-ulcer prevalence by age in males and that of Pulvertaft for peptic-ulcer incidence according to age at diagnosis in males Both these graphs show a maximum frequency in the 50–60 age-group

In our series, by a thorough screening of the practice, we were able to find among our male patients a greater prevalence of peptic ulcer than of non-ulcer dyspepsia—a ratio of 2 8 1 This was an unusual finding, and in our view indicates the extent to which the prevalence (and incidence) of proven peptic ulcer depends on the efficiency of the screening method adopted This, in turn, will depend on the extent to which patients consult their doctor for dyspeptic symptoms This, we know, varies widely according to sex, age, occupation, and social class, and the location of the practice

There is still a need, therefore, as we urged in our paper, for studies of non-ulcer dyspepsia and peptic ulcer in general practice

S LIPETZ
S A SKLAROFF
Edinburgh L STEIN

SIR,—In your leading article of Feb 27 you say that "the frequency of acute perforation in duodenal ulcer in men in York appeared appreciably higher than in Glasgow and Aberdeen but no similar trend was noted in women"

---

[1] *Brit med J* 1955, ii, 172

This is not quite accurate and is, therefore, possibly misleading

The sentence should probably read " appreciably *lower* than in Glasgow and Aberdeen " In connection with the absence of a similar trend in women, it does not appear that this is actually implied by Pulvertaft[1] He shows, in fact, that so far as total perforations are concerned, this condition is more common in women living in the Glasgow area than in the city of York The corresponding figure for the city of Aberdeen for the same years is 7 0 per 100,000 of the female population This is more than twice the Glasgow annual rate and although based on small numbers, since perforation is relatively uncommon amongst women, seems to suggest that there may be a similar trend in women, both for the total perforation-rate and the duodenal perforation-rate

POSTCOITAL EXAMINATION OF SEMEN

SIR,—I am giving you some earlier references[2–5] dealing with the successful treatment of subfertile men, as requested by Mr Dunn (March 12) Dr Farris' book, which he quotes to restate his case, was published in 1950, ten years ago, a good deal of work has been done since then

London, W 1

H A DAVIDSON

ANTI-SMOKING CAMPAIGN

SIR,—Mr Rowntree (March 19) attributes the failure of the Edinburgh campaign to its use of " impersonal and didactic " methods Although we would not dissent from the view that such methods are not in general the best suited to produce changes in attitudes and behaviour, we doubt whether the use of alternative media would have ensured the success of the campaign It seems to us that Mr Rowntree, like many other health educators in this country, attaches so much importance to techniques of presentation that he tends to ignore the psychological implications of the message he seeks to convey and of the behaviour he hopes to change We are convinced that to change smoking habits on any substantial scale does not depend simply upon making the correct choice between alternative media of communication, but rather upon our first acquiring a much deeper understanding than we possess at present of such questions as why people start to smoke, what factors confirm them in their smoking habits, why some smoke a little and others a lot, what part considerations of " risk " and " probability " play in the thinking of people of different levels of education, what emotional reactions are aroused by threats of cancer, and many others, which could be specified

Finally, may we make it clear that we played no part at all in the planning and execution of the campaign? We were concerned only with assessing the success or failure of the campaign, and our roles were analogous to those of auditors We believe, incidentally, that to have sought independent and objective evaluation in this way reflects considerable credit on the Edinburgh Public Health Department

CEREBRAL ANGIOGRAPHY IN THE DIAGNOSIS OF THE ACUTE STROKE

SIR,—Since its inception in 1927, cerebral angiography has expanded enormously, thus marking for Egas Moniz an outstanding and lasting place in the history of medicine If Dandy baked the bread, Moniz buttered it so thickly that the neuroradiologist was evolved, à vous bonne chance With the advance of knowledge and the development of more and more complicated techniques in neurosurgery, chest surgery, and many other branches of medicine, the " one-man-band " was replaced by a team Such a team, a radiologist and two physicians, produced the paper in your issue of March 12 Of their 80 patients submitted to angiography, Dr Bull and his colleagues demonstrated a specific lesion in 33, but more significantly the lesion was not diagnosable clinically in 17, despite the excellence of the physicians This work is of unquestionable value

It is on the " hazards of angiography " that I should like to make a few comments In 1955, in a paper entitled Towards Safer Angiography,[1] I analysed eight published series of angiograms from the point of view of technique, selection, and, more especially, safety I found that in 3128 angiograms, there were 22 deaths and 81 complications, of the complications, 23 were permanent and 58 transient My own series[1] and that of Ver Brugghen[2] were free from mortality or serious complication A year later, Segelov,[3] in his paper, Safe Angiography, recorded a series of 660 angiograms of his own, again without complication, and he reproduced my table

Mainly out of interest, partly from necessity, I took charge of angiography in the Regional Neurosurgical Centre, Liverpool, from 1954 I taught and supervised my trainees, I was free to reject a request for angiography from other clinicians, and I had some excellent anæsthetists Reviewing the work of the past six years, the growth of this investigation is reflected in the following numbers

	Angiograms	*Patients*
1954	273	169
1955	436	290
1956	459	284
1957	528	403
1958	757	543
1959	730	554
Total	3183	2243

There was 1 death (pulmonary embolism), 1 permanent partial hemiparesis (angiography and ventriculography were performed under the same anæsthetic), and 5 other transient complications Each patient was examined at least once during the twenty-four hours following angiography Certainly the stringent method of Bull et al of assessing morbidity and apportioning it to angiography was not applied in this series In a case of vascular glioma, the angiography was followed by an immediate biopsy and if this induced bleeding into the tumour, the paralysis that followed was ascribed to the hæmorrhage, not to the angiography It may be that the incidence of morbidity in our material was in fact greater than indicated, yet in none of the 57 cases of internal carotid or middle cerebral thrombosis was there any increase in the clinical deficit, even when angiography was performed bilaterally

The safety of cerebral angiography depends upon several factors the contrast medium, the personal skill and experience of the angiographer, and my firm personal belief is that a general anæsthetic is another important aid to safety The anæsthetist as a member of the team must understand the problems involved as thoroughly as the clinician and the radiologist There is no room for amateurism and all the trainees must be supervised The clinician who insists on angiography regardless of individual circumstances, the radiologist who for long periods spears every structure in the neck, the anæsthetist ignorant or mindless of a dangerous drop in blood-pressure are all responsible for mortality

---

[1] Sedzimir, C B *J Neurosurg* 1955, 12, 460
[2] Ver Brugghen, A *Arch Neurol Psychiat* 1954, 71, 518
[3] Segelow, J N *J Neurosurg* 1956, 13, 567

Dr Bull and his colleagues investigated patients theoretically representing the greatest potential risks The fact that they had no mortality and reported only 9 transient complications, despite their strict assessment, gives weight to their conclusion that only " centres with facilities should continue their endeavours to assess the place of angiography in the management of acute strokes in relation to the methods of treatment available ", to which I should like to add " and only such centres should use angiography in the management of any condition necessitating this investigation "

Walton Hospital,
Liverpool

C B SEDZIMIR

STAPHYLOCOCCAL INFECTION IN NURSES

SIR,—The article by Dr Davies (March 19) will stimulate the search for ways of decreasing the time that nursing and ancillary staffs spend off duty on account of minor staphylococcal infections

A possible method which seems to have received less attention than it deserves is the use of a plastic " skin " to be sprayed or painted on to form a protective covering over surface lesions This would serve the double purpose of protecting the lesions from further infection or injury and acting as a bacterial barrier to the dissemination of organisms from them Furthermore, it would be technically very simple to incorporate some suitable bactericidal substance in the " skin "

Some investigation has already been done on these lines, notably by Wright,[1] Leader,[2] and Ritelli,[3] but it appears that further research into the use of such methods would be of value

Hythe, Kent

D E STEELE
Medical Adviser, Portland Plastics Ltd

ENVIRONMENTAL STAPHYLOCOCCAL CONTAMINATION

SIR,—I was very interested in the article on staphylococcal contamination by Dr Foster (March 26) What particularly struck me was the " fallout " of contamination shown in fig 3 It is very noticeable that one side of the ward is much more heavily contaminated than the other, and I am moved to wonder why is the ward cleaned by two people, one of whom does floors more efficiently than the other? Are dressings done by two dressing teams, one more conscientious than the other? Are the curtains or screens on each side of the ward made of similar material, and how efficient is curtain cleansing?

I have always thought that a vacuum duster would be a much more useful tool than a floor-washing machine in any hospital, it is deplorable that staff should still be flapping about with dirty fluffy rags, wet or dry, in any surgical ward Bacteria on the floor must have come from beds or dressings and therefore had to be airborne at some time the removal of dust by a vacuum cleaner is better than waiting for it to settle on a washable surface, especially as large quantities of it settle anyway on surfaces unlikely to be washed, such as curtains

As a small comment on ward administration, would it not be safer to put all " dirty " beds together and so concentrate bacteria in one corner of the ward? We always did this twenty years ago in my training school—not that we ever expected to have eight " dirty " cases out of thirty in those days, but if we had they would not have been allowed to spread themselves all over the ward as seems to be the case here

One other point—why no bacterial fallout from one of the beds at all? Had this unfortunate an infection other than *Staph aureus*, and if not, what is the answer?

PERTHES' DISEASE

SIR,—In your issue of March 19 Dr. Cockshott and Dr Palmer, writing from Nigeria and Rhodesia, disapprove of my statement that " the Negro child appears to be immune to Perthes', or at least seems to be only exceptionally affected by it ", which I included in my letter of Feb 13

The only written reference to the frequency of Perthes' among Negro children which I know is given in C W Goff's book[1] He states that among 110,555 coloured children admitted to the Charity Hospital, Louisiana, New Orleans, from 1941 to 1951, not 1 case of Perthes' was recorded, and that in the Hospital for Joint Diseases, New York, with an admission-rate of 20% coloured, not a single Perthes' was ever seen Only the Tennessee Crippled Children's Register reported that they had treated 68 white and 6 Negro children affected by this condition Davies (quoted by Goff), writing from Makerere College Medical School, Kampala, Uganda, reports practically no evidence of Perthes' among the Negro population

All this information was further supported in the discussion at the Latin-American Congress of 1956 in Mexico City of my paper on the blood-supply of the femoral head during growth Dr Oswaldo Campos, in charge of a large children's hospital in Rio de Janeiro, with a large Negro rate of admission, reported that he had hardly ever seen Negro children with Perthes', and Dr Harold Boyd from Memphis corroborated these views

I am sure many will welcome my letter if it may have served to stimulate Dr Cockshott and Dr Palmer to make a survey of real or true Perthes' among Negro children in Ibadan, of course excluding not only sickle-cell anæmia but also subluxation, infective coxitis, and enchondral chondrodystrophy

Nuffield Orthopædic Centre,

J TRUETA

CORPORAL PUNISHMENT

SIR,—We are accustomed to logical fallacies, and sentimentality, in discussions on this subject, but may I suggest that Dr Waycott's article (March 26) reaches an exceptional standard in both respects To quote only two examples of petitio principii, he speaks of " the present agitation for the restoration of corporal punishment based, as it is, on fear and ignorance ", and " as our ideas of criminal responsibility alter " Both statements may be true, but he gives no evidence to support these assertions

He says there is no proof of the deterrent effect of corporal punishment, and indeed that no proof can be given statistically May I suggest that an answer is to be found in Pavlov's work on conditioned reflexes In quite lowly forms of animal life conditioned inhibition of even powerfully attractive stimuli can be readily established by associating them with pain One might reasonably expect in man to inhibit anti-social activities by associating them with pain and other unpleasant experiences Folk wisdom has long since enshrined this in the proverb " A burnt child dreads the fire "

Dr Waycott asserts that the decline in the number of birchings was explicable only because the courts had found the birch useless as a deterrent, alternative explanations are at least tenable It may be that this decline was due to growth of sentimentality in magistrates, and to a possibly unwarranted belief in the value of psychological methods of tackling the offender His description of the technique of corporal punishment, quoted from the Cadogan report, is unpleasant, but this is irrelevant to the merits of the punishment As a young practitioner I found it unpleasant to give anæsthetics for dental extractions, or for avulsion of a toenail, but as a rational being I recognised the necessity of such procedures

Lastly, some of us reactionaries are not very much interested in his point as to the value or otherwise of corporal punishment in constructive treatment of offenders we are more selfishly concerned with whether it tends to make life more secure for us and our families, and we are even sceptical as to the value of more refined methods in remodelling the offender's mind. Physiology does show the obvious—that one entry to the consciousness of man is via the sensory nervous system!

CRYPTOGENIC LIVER ABSCESS

SIR,—The interesting and instructive article by Dr Stokes (Feb 13) establishes the remarkable rarity of this condition We wish to mention, therefore, a recent case involving left, rather than right, hepatic lobe, investigated and treated in a small suburban hospital of 130 beds

A formerly healthy 30-year-old man was admitted on Nov 16, 1959, suffering a diurnal febrile illness dating from Oct. 28 Symptoms consisted of daily fever to 104°F, generalised headache, malaise, nausea with occasional vomiting, and finally aching lower sternal and left subcostal pain. Guarding of the abdomen was marked, but an area of resistance seemed apparent under the left costal margin, although neither liver nor spleen could be certainly felt. In a battery of laboratory investigations only a white-cell count of 16,000 per c.mm., later rising to 33,000 (predominantly granulocytic), and two positive blood-cultures showing a heavy pure growth of microaerophilic streptococci were revealing Response to large daily doses of penicillin was satisfactory

Recovery appeared complete, and the patient was discharged home on Dec. 5 Readmission, however, became urgently necessary on Dec. 17, because of weight-loss, recurrent fever, and increasing upper abdominal pain. Hæmoglobin had dropped from 89% to 78% and the white count had again risen to 13,500 Further blood-cultures were sterile The liver was, on this occasion, palpable and acutely tender, particularly over left lobe. Under cover of penicillin, surgical drainage of an orange-sized left hepatic abscess was performed Jan. 9 An attempt to open the mass extraperitoneally was not possible. Culture of thick yellowish-green purulent material from the abscess revealed the organism obtained on two former blood-cultures Subsequent recovery has been satisfactory and gratifying

Toronto WILLIAM B PHAIR.

PLACENTA PRÆVIA

SIR,—In reply to Dr Blair Hartley (March 19), I would say that I do not need to go to Manchester because I have already been, have seen the beautiful X-rays produced in his department, and realise how valuable his assistance can be How many obstetrical units, even in the United Kingdom, and still less in the underdeveloped parts of the world, have the skilled advice that is available in Saint Mary's Hospital, Manchester? Therefore, until such highly specialised radiology is widely available I think it wiser to teach our students, and still more so our future consultants, to depend on careful clinical observation rather than inadequate radiology

Dr Blair Hartley criticises me for quoting him out of context. I could also complain. Had he continued reading my article he would have found that I stated "If I am right, the differentiation between non-toxic accidental hæmorrhage and hæmorrhage from placenta prævia is of little practical value at this period of gestation, since the patient should in any case be retained in hospital for investigation and observation."

I may not have made my point clear, but I was trying to show where Mr Percival and I differed. If Mr Percival can demonstrate the placenta by radiological methods in the upper uterine segment he allows a certain number of cases of antepartum hæmorrhage to return home so as to utilise available antenatal beds

As we do not know the extent of the risk to which we submit the unborn child when we expose it to X-rays (and some authorities state that it is considerable), it is doubtful if exposure for four films is justified when the same information can be obtained in a large proportion of cases by careful clinical examination.

The use of placentography in the occasional case not elucidated by clinical examination to differentiate between placenta prævia and accidental hæmorrhage is still hardly justifiable when, as I believe, both types of case should be retained under observation in hospital

An X-ray is advisable if there is any question of fœtal abnormality, because the presence of an abnormal fœtus will alter the future treatment

HEPATITIS AFTER INOCULATION

SIR,—A patient who submits to an inoculation has a right to expect that all reasonable safety measures have been taken It is now 10 years since Evans and Spooner showed that aspiration of tissue fluid into the barrel of a syringe occurs when the needle is removed after an injection, and, as you stress in your leader of March 5, the only method of eliminating the risk of post-inoculation hepatitis is to use a separate sterile syringe and needle for each person inoculated You state, however, that this is admittedly an inconvenient procedure

At the inoculation clinic at this hospital we have been using a separate syringe and needle for each patient inoculated since 1953 Approximately 30,000 people are inoculated annually, and as means of sterilisation was already available in the hospital, all that was needed to start the scheme was the purchase of about 300 syringes These are packed in the ordinary blood-transfusion boxes between layers of lint and sterilised in the autoclave the needles are sterilised separately in the hot-air oven

Before the clinic begins the sister-in-charge loads each syringe with the material required, fits a needle which is covered with a sterile tube, and the patients are called in in small groups We find this much more convenient than the old method and for a relatively small cost syringe-transmitted hepatitis has been completely eliminated

Hospital for Tropical Diseases,
London, N W 1 L ROODYN

SIR,—Your leading article stated "inoculation clinics must be better organised with enough helpers to sterilise and load syringes" Subsequently, you said that boiling will be found less practicable than dry-heat sterilisation

I had understood that, in fact, the main disadvantage of boiling was not its impracticability but the fact that it did not sterilise the syringe, and so did not provide a guarantee against the risk of transmission of hepatitis by this means If this is correct, the implications of your article would seem to be misleading

Perhaps some clear guidance on this point will be given in the new M.R.C memorandum

M J PLEYDELL
Health Department County Medical Officer
Oxford of Health

SIR,—As you say, the information contained in your valuable leading article has been well known to the medical profession for several years[1] Undoubtedly the principle of one patient, one sterile needle, and one sterile syringe is an attainable ideal in the prevention of post-injection hepatitis

May I suggest that it is necessary to tackle the entire subject —namely, the prevention of hepatitis the ætiological agent of which is transmitted to patients by means directed primarily to the saving of life, the maintenance of health, the comfort of the patient, and the prevention of disease? This type of jaundice may well result from, for example, a saline and/or glucose intravenous drip using equipment imperfectly cleaned and sterilised after a blood-transfusion, or the administration of plasma, to another patient. Because of this it may be suggested that as far as possible all such apparatus should be discarded after each blood-transfusion Tattooing is another long-recognised manner of acquiring this type of hepatitis, several examples of which I have seen in recent years overseas

PRIVATE PATIENTS IN THE NATIONAL SCHEME

SIR,—If there are indeed, as "Former Locum" implies in his letter of March 26, doctors who accept fees from their own N H S patients, they must be incredibly foolhardy By so doing not only do they commit a gross breach of their terms of service they also lay themselves wide open to blackmail

Crediton, Devon L N JACKSON

DIURETIC EFFECT OF SPIROLACTONE SC-9420

SIR,—In *The Lancet* of March 12, Dr Clowdus and his colleagues discussed the treatment of refractory ascites with SC-9420 Here are further data

We have treated with SC-9420 11 patients with cirrhotic ascites refractory to corticoids and thiazide diuretics In 9, a dramatic improvement was obtained, natriuresis increased from below 10 mEq to a maximum of 240 mEq per twenty-four hours, with SC-9420 alone, making unnecessary the use of other diuretics, in 1, a moderate improvement only was achieved, and 1 case was a failure However, because of the impossibility of obtaining, in most cases, a return to normal of aldosterone secretion, sodium retention and œdema reappeared several days after stopping SC-9420 Therefore, SC-9420 courses were repeated at intervals Satisfactory control of œdema can be achieved for a long time, without maintaining strict low-sodium diet, the tolerance of SC-9420 is excellent and its activity remains unabated In our experience, the use of cortisone-like steroids[1] first, then (in case of failure) spirolactone, has entirely modified the course of cirrhotic œdemas, if not of liver cirrhosis

Our first results were published[2] in October, 1959

OLD ST THOMAS'S HOSPITAL OPERATING-THEATRE

SIR,—Some 3 years ago the female operating-theatre of old St Thomas's Hospital was discovered by Mr Raymond Russell in the roof space of the Chapter House in St Thomas's Street Many of your readers may not know that St Thomas's Hospital used to be on the opposite side of the street to Guy's Hospital until it was forced to move by the coming of the railways in 1860 In the *Guy's Hospital Reports* (1957, 106, 133) Mr Raymond Russell has written a full account of this early 19th-century operating-theatre

As the theatre is of considerable historical interest and importance a committee has been formed to restore it to its former state Much research is necessary and we feel that some of your readers may be able to help us in two ways

(1) If they know of any drawings, paintings, photographs, &c, of the old St Thomas's female operating-theatre or of any other information about it

(2) If they know of any early 19th-century theatre equipment or furniture such as side-tables, wash-bowls, hanging lamps, chairs or seats, &c., &c

It is probable that there is much material of this sort tucked away in hospitals around the country and they could prove invaluable in the restoration

INTRAVASCULAR CLOTTING

SIR,—It is gratifying that my letters of Jan 16 and 30 have prompted replies, because only by an exchange of views can a better mutual understanding of such a complicated problem as intravascular clotting be attained

I fully agree with Dr Sevitt (Feb 13) that venous stasis plays a major ætiological role in deep venous thrombosis, and I feel that maintenance of good venous circulation may be far more important than anticoagulants for preventing thrombosis in certain instances Stasis, however, cannot initiate a clot when the endothelium is normal Blood remains completely fluid for a surprisingly long period in a silicone-coated container, and certainly this crude surface is not comparable in efficiency to the healthy endothelial lining of the vascular system Probably the only known agent in the blood that can per se initiate the clotting reaction is erythrocytin,[1] but it is questionable whether enough can escape from intact erythrocytes to be of any consequence The ubiquitous distribution of preformed thromboplastin in body tissues including the walls of the blood vessels offers a clue The release of thromboplastin from the vessel wall does not require a gross injury—very likely, prolonged anoxia may suffice—to induce enough temporary alteration in the endothelium for this to happen Stasis alone does not explain the initiation of the thrombus, its attachment to the vessel wall, its structure and growth in the bloodstream, though it often plays an exceedingly important ætiological role Intravascular clotting can and does occur, however, in the absence of demonstrable stasis as illustrated by thrombophlebitis migrans

In regard to the letter of Dr Walker and Dr Matthews (Feb 13), I am certain that they "meant in no way to detract from the basic physiological and practical diagnostic merits of the one-stage prothrombin-time technique", for if they had, they would have condemned the thrombotest and all the multifarious modifications of the original method The crucial question is whether my method carried out according to my specific directions has the shortcomings that necessitate its replacement for controlling anticoagulant therapy

According to Professor Owren (Nov 7) my method "is not ideal" because "it requires experience and skill" and "the quality of the thromboplastin is of decisive importance" When I developed the test, I took these factors into careful consideration. After years of study, I succeeded in working out a simple method for obtaining a thromboplastin reagent which gives a prothrombin-time of 11 5–12 seconds consistently The directions for the preparation have been explicitly described, and no laboratory, therefore, need be dependent on any particular commercial preparation

The basic disagreement, however, is brought out by Dr Walker and Dr Matthews' statement "Surely he would not deny that unduly severe depression of true prothrombin and of factor IX can exist unrevealed by the one-stage test " I emphatically deny the correctness of this statement Some time ago the erroneous claim was made that the one-stage method was insensitive to prothrombin, and this has been repeated often enough to have acquired some of the prerogative of a fact. I have repeatedly studied two brothers with congenital hypoprothrombinæmia The diagnosis has been established both by my modified prothrombin-time tests and by the Iowa two-stage method The prothrombin-time of these boys is usually 20–24 seconds, and has never been shorter than 19 seconds, both boys are mild bleeders. The third patient with congenital hypoprothrombinæmia vera is a girl, age 10, whose prothrombin-time averages 60 seconds. She has required a plasma transfusion every five weeks since birth. Thus, the test serves as a delicate and quantitative indicator of the bleeding state in pure prothrombin deficiency.

---

[1] Vesin P *Arch Mal App Dig* 1959, 12, 1497

[2] Vesin, P, et al *Bull Soc méd Hôp Paris*, 1959, 24-25, 826

[1] Quick, A J *Amer J med Sci* 1960, 239, 51

When the prothrombin-time is longer than 30 seconds, a bleeding tendency occurs whether the defect is lack of prothrombin, factors v or vii, or Stuart-Prower factor. Factor ix does not affect the test, since the prothrombin-time is normal even in severe hæmophilia B (Christmas disease). It has been the observation of Dr David LaFond, who has been working in my laboratory, that only in long-term anticoagulant therapy is factor ix occasionally decreased significantly. Under these conditions, however, the decrease of prothrombin and factor vii so overshadows the former that the prothrombin-time remains a reliable guide.

I do not doubt that bleeding occurs at times when the prothrombin-time appears to be in the therapeutic range. What is puzzling to me is why it does not occur more frequently when the test is performed in such a manner that a normal range of 11–20 seconds is permitted.

The one-stage test was developed for diagnostic purposes; later, it proved to be an important tool of research. I was not consulted when it was introduced to control anticoagulant therapy. The evaluation of the test for this purpose belongs primarily to those who employ it. If it is the consensus of those who carry out the procedure carefully with a properly prepared thromboplastin reagent that the Quick test is unreliable, I shall be among the first to recommend its withdrawal from the clinical laboratory.

ABSENT CIRCULATORY REFLEXES IN DIABETIC NEURITIS

SIR,—I wonder if Professor Sharpey-Schafer and Dr Taylor (March 12) are justified in concluding that "severity and duration of the diabetic state were not factors" in the loss of circulatory reflexes in diabetic neuritis. What they have shown is that some patients developed the neuritis within a year of diabetes being diagnosed—i.e., that the condition can appear early in the (recognised) course of diabetes. But in order to conclude that duration is not a factor in the ætiology of the neuritis they would have to show that their patients with neuritis have not had diabetes for longer, on average, than those without. There is admittedly some support for their conclusion from the fact that the seventeen patients with complete loss of circulatory reflexes had had diabetes for no longer than the fourteen with only partial loss (an average of 9 and 12$^1/_2$ years respectively).

Professor Sharpey-Schafer and Dr Taylor present no data for the "severity" of diabetes among their patients without neuritis, so it is impossible to say that it is not a factor. There are varying definitions of "severity" in diabetes, the most helpful is dependance upon treatment. A patient on a small dose of insulin may be more "severe" than one on a large dose. Thus their category "controlled on moderate doses of insulin" does not necessarily represent a group of equal severity. What they are presumably trying to measure is control of the disease, which is even more difficult.

The authors do not comment on the predominance of men among their cases (twenty-five to six) which, if they were selected from a representative group of diabetics, would correspond to a sex-ratio of about 6 : 1. (All the patients, except one, with complete loss of circulatory reflexes were men.) Nor do they remark upon the ages of their patients. Only three of thirty-one patients were under forty-five years old. Without knowing the age-distribution of the patients from whom these thirty-one were selected one cannot say whether age is an ætiological factor, but in most diabetic clinics more than 10% of the patients are under forty-five, especially among the men.

TOXIC MARROW FAILURE TREATED BY A HOMOGRAFT OF FŒTAL HÆMOPOIETIC TISSUE

SIR,—We were interested to read of the use of fœtal liver transfusion in combating marrow depression due to thiotepa.[1] Three of our patients with advanced carcinoma of the breast who were given thiotepa in doses similar to that used by Dr Bridges and his colleagues developed severe marrow depression which appeared to respond to prednisone alone.

In one patient the total white-cell count fell to 700 per c.mm. and the platelet-count to 40,000 per c.mm. She was well six months later, having discharged herself from a terminal home. Another patient's total white-cell count fell to 750 per c.mm. and the platelets to 22,000 per c.mm. She was well seven months later. In the third case the total white-cell count fell to 600 per c.mm. and the platelet-count to 15,000 per c.mm. She had a hæmatological remission but died five weeks later.

In our patients the blood-count improvement coincided with the oral administration of prednisone 30 mg. daily. In the case quoted by Bridges et al. methylprednisolone was started the day before the fœtal liver transfusion. We wonder how much the latter contributed to the hæmatological recovery.

SNAKEBITE

SIR,—The word "envenomation", which occurs on p. 690 of your issue of March 26, is not to be found in Chambers or in The Shorter Oxford English Dictionary, nor likely to be found in any other (though there is a verb to envenom, nearly always used metaphorically). Has it any advantage over "poisoning"?

London, S.W.20
JOHN PENMAN

RENAL TUBULAR FUNCTION IN HYPERPARATHYROIDISM

SIR,—Dr Fourman and his colleagues (March 19) raise the interesting possibility that defects of renal tubular function may be of value in separating patients with hyperparathyroidism from other patients with renal calculi. Since hearing them speak on this subject, I have had the opportunity to study two patients with hyperparathyroidism, and a third patient who almost certainly has hyperparathyroidism.

The test differed slightly from theirs in that the patients were deprived of water for 14–16 hours before the mannitol infusion, and 2 hours before the infusion they were given a single dose of vasopressin. No water was given during the mannitol infusion. Under these conditions my hyperparathyroid patients (see table) behaved in response to mannitol infusion

Patients	Urine (mOsm. per l.)		$T^{c}_{H_2O}$	Urine pH after NH_4Cl
	Max.	Min.		
1	690	455	−4·3	5·7*
2	640	565	−4·0	5·0
3	658	425	−5·07	4·9
4†	280	254	−0·23	6·4

* In response to 0·05 g. NH_4Cl per kg. body-weight.
† Renal tubular acidosis. Patients 1, 2, and 3 have hyperparathyroidism.

---

[1] Bridges, J. B., Bridges, J. M., Edelstyn, G. J. A., Lyons, A. R., Nelson, M. G. *Lancet*, March 19, 1960, p. 629.

like their patients without hyperparathyroidism Their renal function was in other respects unimpaired A young patient with renal stones but without hyperparathyroidism was also studied, and she performed very poorly in response to mannitol infusion. However, it was later decided that her calculi were due to renal tubular acidosis

The response to ammonium-chloride loading was also tested, and the results are included in the table Two of the hyperparathyroid subjects behaved normally in this respect also, the third one was given a lower dose of ammonium chloride than is suggested by Fourman et al

My results suggest that not all hyperparathyroid subjects behave abnormally during osmotic diuresis induced by mannitol infusion, and following ammonium-chloride loading However, it should be remembered that the conditions under which I infused mannitol differed slightly from those used by Fourman et al

Obituary

DOUGLAS JAMES ACWORTH KERR

M D Edin, F R C P E, D P H, F R S E

Dr Douglas Kerr, regius professor of forensic medicine in the University of Edinburgh since 1953, died on March 23 at the age of 65

He was born at Bradford and was educated at St Paul's School, London, and the University of Edinburgh He was wounded in 1914 while serving with the Royal Artillery, and transferred to an anti-aircraft unit of the Royal Flying Corps In 1918 he returned to Edinburgh to complete his studies, graduating M B in 1920 After qualifying he held resident posts at Edinburgh Royal Infirmary and in 1922 took the D P H In 1927 he took the M D with commendation and was elected F R C P E Two years later he was appointed police surgeon and medical referee to the City of Edinburgh, an appointment which he continued to hold after he succeeded Sir Sydney Smith in the chair of forensic medicine in 1953

Professor Kerr was well known in Scotland as a medical witness who was both expert and fair His *Textbook of Forensic Medicine*, first published in 1935, was illustrated with photographs and cases from his wide medicolegal practice Though originally written for students—he was for many years a lecturer at Surgeons' Hall—it has offered useful guidance to many practitioners, and a sixth edition was published in 1957 Professor Kerr was the representative of the Royal College of Physicians of Edinburgh on the General Medical Council

F S F writes

" Douglas Kerr had a high sense of duty and walked very steadfastly in accordance with the principles in which he believed He was a man of great courage By reason of his work as medical referee he was well known by repute to a wide circle, but he was a reserved man who shunned the limelight He had, however, great gifts of sympathy, understanding, and compassion and he had his own unobtrusive way of expressing this very real aspect of his personality "

In 1935 Professor Kerr married Phyllis McGregor, who survives him with two sons and a daughter

MONTY TOOHEY

M D Dubl, M R C P, D C H

Dr Toohey, consultant physician at New End Hospital, London, died on March 21 at the age of 45

Dr Toohey was born in Limerick and he was educated at Wesley College and Trinity College, Dublin After graduating M B in 1936, he held resident hospital appointments in Dublin and at Booth Hall, Manchester, and took the D C H in 1938 and the M R C P in 1939 During the late war he served with the R A M C in India, France, and the Far East, and was promoted to lieut -colonel in charge of a medical division. After the war, he became consultant physician to New End Hospital, and thenceforward his main medical activities were centred there

During the last four or five years, he had made a special study of long-term treatment of atherosclerosis and ischæmic heart disease by anticoagulants, and his enthusiasm was responsible for the establishment at New End Hospital of a large, well organised clinic He wrote many articles for scientific and medical journals on the treatment of ischæmic heart-disease by anticoagulants and methods of control, and earlier he published a book, *Medicine for Nurses*, which has become a standard work

J E P writes

" A little over three years ago Dr Toohey's health began to fail and though he knew that he should have curtailed his activities both in his clinic and in research, the fact only seemed to spur him on to greater efforts He took a great interest in the activities of his hospital and he was admired and respected by his colleagues and by his patients and staff His loss to the hospital and to medicine is something one can hardly gauge, though the results already obtained at his clinic must ultimately prove of the greatest value in the final evaluation of the treatment of coronary disease "

Dr Toohey is survived by his widow and two daughters

Notes and News

ADMISSION IN LABOUR

THE London executive council have been considering a complaint from an obstetric consultant alleging that, because a general practitioner had failed to make arrangements for a patient to be confined in hospital, the patient was admitted to the consultant's unit through the Emergency Bed Service when she was already in labour The circumstances of the case, as ascertained by the executive council, were as follows

The patient first went to her family doctor at the end of March, 1959, when she was 20-22 weeks pregnant, as a primigravida with home conditions unsuitable for confinement She was sent with a letter to the antenatal clinic at Lewisham Hospital, but the hospital would not book her for a confinement with them She did not return to the family doctor until June 15, when she brought a letter from a London County Council clinic saying that the patient had been unable to make arrangements for her confinement in hospital and that she had been instructed to consult her family doctor with a view to arrangements being made for her admission to hospital through the Emergency Bed Service when labour started or when any emergency arose Late in July, 1959, the patient's landlady informed the family doctor that the patient would not be allowed to have her baby at home She also implied that the patient was not attending any clinic The doctor, therefore, asked the patient to come to his surgery, which she did on July 29 She told the doctor that she had been to the clinic and expected to be admitted to hospital when in labour as advised by the clinic The doctor arranged to see her again a fortnight later but she went into labour on Aug 9 and was admitted through the E B S to hospital "at the request of her family doctor"

In these circumstances the executive council found that the general practitioner had no alternative but to seek a bed for his patient through the E B S at the time labour began This was the only way at present open to a general practitioner to get a patient into hospital when an early booking had not been possible. The executive council appreciated that this procedure inconvenienced the running of the maternity units, but the blame, in their view, lay neither with the general practitioner nor with the L C C clinic but with the regional hospital board, which had not reserved enough beds to allow a margin for obstetric and social emergencies

SHORTAGE OF MIDWIVES

THE Association of Hospital Management Committees have sent a memorandum to the Ministry of Health setting out their views on this serious problem, which is likely to become even more acute during the next ten years They agree with the Cranbrook Committee that something should be done without delay to avoid the present waste of money and nurses by training so many recruits who do not intend to adopt midwifery as a career The inclusion of a short midwifery course in the basic nursing training, which is at present being discussed by the Central Midwives Board and the General Nursing Council, would in the Association's view be a potent remedy and would open up the possibility of a return to a single comprehensive course of training in midwifery Employing authorities could also help by asking for a qualification in midwifery only in posts where it is really needed.

The Association would like to encourage recruits from among assistant nurses and women who are not registered nurses Increases in salary may not be the only way of attracting and retaining staff, but the Association point out that the profession is still dissatisfied with differentials, and where promotion prospects are limited, financial compensations should be offered Inducement payments for small and peripheral hospitals have been rejected or abandoned, but the Association suggest that schemes of this kind should be reconsidered

NEW FILMS

Two films have lately been completed by the photographic and film unit of the Royal Society of Medicine

The first, *They Breathe Again* (16 mm, black-and-white, sound), runs for about 25 minutes It was made at the respiratory unit of Rush Green Hospital, Romford, and its purpose is to demonstrate—to general practitioners, hospital residents, nurses, and medical students—the principles of treatment of respiratory, bulbar, and bulborespiratory poliomyelitis It does this, on the whole, very well, though some time is wasted on inessentials such as shots of an ambulance making its journeys, and of crowds in Trafalgar Square (to illustrate the point that many people have poliomyelitis without being ill)

In the first section, dealing with respiratory poliomyelitis, a team is shown collecting a patient from another hospital and transferring her to the unit, with support from an Oxford inflating bellows en route The principle of a cabinet respirator is briefly explained with help from an animated diagram, and the patient is shown being expertly transferred to the cabinet respirator The maintenance of ventilation by intermittent positive-pressure respiration (I P P R.), when the cabinet has to be opened, is also shown The importance of preventing and treating collapse of lung, by tilting and physiotherapy, is given due emphasis For patients less severely afflicted, the cuirass respirator, the rocking-bed, and glossopharyngeal breathing are briefly shown

The next section, dealing with bulbar poliomyelitis, is introduced by an animated diagram showing the mechanism of swallowing This is followed by a convincing shot of the effect of forcing a drink into a patient with bulbar involvement The use of a Ryle's tube and nursing in the prone position are shown

In the third section, on bulborespiratory poliomyelitis, the necessity for early tracheostomy with a cuffed tube and I P P.R. is emphasised, and several mechanical ventilators are shown in action

The importance of having enough trained nurses to give each of these exacting cases adequate attention is rightly indicated Finally, the place of vaccine in reducing the incidence of respiratory poliomyelitis is discreetly mentioned.

This film fulfils its purpose well, and it gets a great deal into a short time There are, however, some noteworthy omissions Little guidance is given to the recognition of early bulbar involvement, nothing is said of the biochemical control of long-term cases or of the regulation of artificial respiration, and for spirometry one could have wished to see the Wright respiratory meter shown instead of the Dräger 'Volumeter', for it is lighter and more accurate The commentary is spoken with great clarity by Frank Phillips Copies are available from Rush Green Hospital, Romford, Essex

The second film is a 16 mm 'Ektachrome' sound film entitled *Upper Lobectomy with Sleeve Resection of the Main Bronchus*, which runs for about 25 minutes The medical adviser was Sir Clement Price Thomas, and the audience is treated to an impressive demonstration of surgical skill

The various stages of the operation are shown and described—rib resection, dissection of pulmonary vessels, removal of paratracheal glands, division of vagus nerve, exploratory dissection of lung tissue, division of bronchus, removal of diseased lobe, end-to-end bronchial anastomosis But those who are not practising thoracic surgeons are liable soon to be lost in repetitive scenes of featureless lung tissue, scissors, swabs, and dissecting-forceps, and the commentator's explanation of what is being done has to be taken on trust

This is essentially a "how-I-do-it" film, and it will probably appeal strongly only to those who have to do it. For these it should prove extremely valuable, for the photography is good, the field is little encumbered by hands or heads, and the steps are clearly described

On June 28 the degree of LL D is to be conferred on Prof J M Webster

University of Edinburgh

The status of honorary senior lecturer in the department of ophthalmology has been conferred on Dr N L Stokoe

Royal College of Surgeons of Edinburgh

On Friday, May 6, at 3 30 P M, Dr A Rae Gilchrist will give a lecture at the college on the cardiac patient as a surgical problem

Royal College of Obstetricians and Gynæcologists

Mr T N MacGregor has been appointed Sims-Black professor He will visit Australia and New Zealand in 1961

The college move to their new building on April 2, and the address is now Sussex Place, Regent's Park, London, N W 1 (AMBassador 5425)

Royal Society

The 25 newly elected fellows of this society include

Prof J N Davidson, Gardiner professor of physiological chemistry, University of Glasgow, Sir Stewart Duke-Elder, ophthalmic surgeon and director of research in the University of London at the Institute of Ophthalmology, Dr D G Evans, director, Biological Standards Control Laboratory (Medical Research Council), London, Dr P A Gorer, reader in experimental pathology in the University of London at Guy's Hospital Medical School, Dr H E Huxley, member of the staff of the Medical Research Council department of biophysics in the University of London at University College, Dr J C Kendrew, deputy director, Medical Research Council unit for molecular biology at the Cavendish Laboratory, Cambridge, Sir George Pickering, regius professor of medicine, University of Oxford, Dr E N Willmer, reader in histology, University of Cambridge

Westminster Medical School

Dr R I S Bayliss has succeeded Mr H E Harding as dean of this medical school

Order of St John of Jerusalem

The Queen has sanctioned the following promotions in, and appointments to, this Order

As Commander (Brother) —J S Grant, M.D , F R C S

As Officers —L E Claremont, M R C S , Pang Hok Ko, J A Dryden, M B Major-General W D Hughes, C B E , F R C P I , Q H P , Colonel J C Reed, C B E M B , A L Potter, M D , M R C O G

International Congress of Otorhinolaryngology

This congress will be held from July 23 to 29, 1961, in Paris Further particulars may be had from Dr Henry Guillon, 6, avenue MacMahon, Paris, 17^{e}

International Congress of Rheumatology

This congress will be held in Rome, from Sept 4 to 7, 1961 Further particulars may be had from the general secretary, Prof C B Ballabio, Clinica Medica Generale, Via F Sforza 35, Milan, Italy

Cancer Education

The Central Council for Health Education has set up an advisory committee on cancer education which will correlate activities, act as a clearing-house for information, provide a forum for discussion, and organise conferences and other activities The committee will work from the office of the Council, Tavistock House North, London, W C 1

National Association for Mental Health

This association will hold a conference on psychiatry for general practitioners from May 27 to 29, in London The speakers will be Dr H V Dicks, Dr John Fry, Dr T F Main, Dr Desmond O'Neill, Dr William Sargant, Dr D Stafford-Clark, Dr D W Winnicott, and Dr Kenneth Cameron Further particulars may be had from the education secretary of the association, 39, Queen Anne Street, W 1

Prof John Bruce has been appointed honorary surgeon to the Queen in Scotland in succession to Sir James Learmonth, who has resigned Sir James has become extra surgeon to the Queen

The Ernest and Minnie Dawson Cancer Trust is to arrange a competition for general practitioners to take the form of a thesis on cancer Further particulars will be found in our advertisement columns

The Oliver Bird prize for 1959 has been awarded to Miss H M Bruce, of the National Institute for Medical Research, London, for a series of papers on an exteroceptive block to pregnancy

There will be a meeting for general practitioners in the outpatient department, King's College Hospital, Denmark Hill, London, S E 5, on Sunday, April 10, at 10 30 A M

The Belmont Hospital Clinical Society will hold a meeting on Thursday, April 7, at 8 P M , at the hospital, Sutton, Surrey Dr A. Russell Lee will speak on the intrafamilial environment of the schizophrenic

A meeting of the subscribers of the Naval Medical Compassionate Fund will be held at 2 45 P M on May 13, at the Medical Department of the Navy, Queen Anne's Mansions, St James's Park, London, S W 1, to elect six directors

Stammerers are to hold a symposium on the Technique of Speaking, at Goldsmiths' College, New Cross, London, S E 14, on Wednesday, April 6, at 6 30 P M As adult students of Mr H V Hemery's classes at the college, they will read prepared speeches or speak impromptu

For the Association of Medical Advisers in the Pharmaceutical Industry, *which was formed some three years ago*, a course was given on Feb 25 and 26 by the faculty of medicine of the University of Glasgow and the Royal Faculty of Physicians and Surgeons The subjects were corticosteroids and hypertension

Diary of the Week

APRIL 3 TO 9

Monday, 4th

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln s Inn Fields, W C 2
5 P M Mr J H Hovell Surgical Treatment of Mandibular Prognathism With Special Reference to Functional Anatomical Considerations in Diagnosis and Treatment Planning (Hunterian lecture)
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray s Inn Road, W C 1
6 P M *Prof L B W Jonkees (Amsterdam)* Physiology of the Static Labyrinth

Tuesday, 5th

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S W 1
5 P M Dr D Evan Bedford Disorders of the Pulmonary Circulation (First of two Lumleian lectures)
ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P M Prof Arnold Sorsby Blindness in Children—Genetic Aspects

Wednesday, 6th

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P M Mr R A Mogg Renal and Ureteric Neoplasms

THE REACTION TO SUBCUTANEOUS DRAINAGE IN ANASARCA

D. W. Vere
M.B. Lond., M.R.C.P.
SENIOR LECTURER IN MEDICINE

C. E. King
B.A. Cantab
BIOCHEMIST

MEDICAL UNIT, THE LONDON HOSPITAL, LONDON, E.1

The disorder of body-fluid volume control in œdema is one of the most baffling aspects of renal disease. The apparent indifference of the kidney to the fluid sequestered in the interstitial tissue and serous cavities led in the past to the conclusion that the kidney was little concerned in volume control—a view now known to be untrue. More recently it has been suggested that withdrawal of œdema fluid is without biochemical effects on the body because the fluid is an isotonic saline solution whose composition is nearly that of protein-free plasma (Friese and Thayer 1950, Hardwick 1958). The observations reported here show, however, that metabolic effects may be seen when less than 10% of the œdema fluid has been removed, and during a large drainage may lead to serious renal damage and circulatory collapse. These metabolic changes during subcutaneous drainage involve the kidney, the extracellular fluid, and the cells.

Description of Cases

Subcutaneous drainage was carried out on ten occasions in seven patients. The clinical features are summarised in table I. We saw all the cases except nos. 6 and 7, who are included because they illustrate the development of serious collapse after drainage.

Four male and three female patients were studied. All had gross œdema due to chronic nephritis except case 7 in whom right heart-failure was the cause. Their ages fell between 40 and 65. Cardiac failure was present in two of the nephritic patients (4 and 5), but there was hypoproteinæmia in all. The blood-pressure was raised in each of the patients with nephritis. Tests of renal function included the maximum urine-urea concentration and the creatinine clearance. These were normal in two subjects (2 and 6) and impaired in the others. In the patient with right heart-failure alone, a low creatinine clearance was associated with good concentrating-power. From 4·5 to 66 litres of œdema fluid were removed over 3 to 17 days. Histological confirmation of the clinical diagnosis was available in every patient except case 3. Hodgkin's disease in case 5 appeared to be a coincidental illness unrelated to the renal disorder.

Methods

In eight of the ten drainage periods, biochemical estimations were made in the metabolic laboratory. Patients were nursed in the metabolic ward, with full facilities for balance studies, on three occasions, and in the other instances in a general ward. The two patients not seen by us were investigated in the hospital clinical laboratory. Repeated drainage in the same patient is indicated by placing a and b after the case number. Continuous balance studies were often impracticable owing to the clinical state of the patients. Two became seriously disorientated during part of the investigation so that a planned regime had to be abandoned. Wherever possible, urine collections were made under toluene, and blood was drawn at the same hour of the day. The patients were kept semirecumbent in a cardiac bed till the legs were tense; drainage was then carried out by making about twelve shallow scratches through the epidermis. A low-salt diet (1 g. Na daily) was given, with a constant potassium and nitrogen intake (cases 6 and 7 excepted). Some patients had a little vomiting towards the end of drainage but this symptom was severe only in case 4. In two instances (3a and 4) sodium supplements were given during drainage, and in three (1b, 3a, and 3b) potassium, in an attempt to correct a known or probable electrolyte depletion. Treatment was not changed during the period of drainage except in cases 3a and 7. Water intake was fixed in cases 1a, 2, and 3a, but was free in the others.

Chemical methods were those used in standard laboratory practice. Sodium and potassium were measured by flame photometry, chloride

TABLE I—CLINICAL DATA BEFORE SUBCUTANEOUS DRAINAGE. (a) AND (b) REPRESENT TWO DRAINAGES ON THE SAME PATIENT

Case	Age and sex	Diagnosis (histologically confirmed*)	Volume drained (ml.)	Days' drainage	Plasma-albumin (g. per 100 ml.)	Months of œdema	Urine deposit and culture	Renal function			Blood-pressure (mm. Hg)	Heart-failure
								Blood-urea (mg. per 100 ml.)	Maximum urine urea (g. per l.)	Creatinine clearance (ml. per min.)

by mercuric-nitrate titration (Schales and Schales 1941) and creatinine in most cases by picrate colour after adsorption (Ralston, 1955) In some early studies (case 2) the older Jaffe method was used Total plasma-protein was measured by the Kjeldahl method and albumin by salting-out Urine protein was estimated by Kjeldahl after sulphosalicyclic acid precipitation Ammonium and urea were measured by microdiffusion methods (Conway 1947), and calcium by standard oxalate precipitation Hæmatocrits were determined by centrifuging for 55 minutes at 3000 r p m

Estimations of extracellular fluid and plasma volume were omitted since it was felt that in patients with extreme œdema and serous effusions equilibration of a foreign substance with body fluids would be prolonged and incomplete Even the use of labelled-albumin plasma-volume measurements may be misleading in subjects with heavy proteinuria and a rapid albumin turnover It was decided that the hæmatocrit and plasma-protein concentration would be the best guide to changes occurring over a few days, although it is realised that enhanced protein catabolism and the liability to hæmorrhage may affect these measurements

Results

Metabolic changes of considerable variety and complexity were observed both during and after the periods of drainage Nevertheless, in most cases it was possible to detect a regularly occurring pattern associated with a consistent sequence of clinical events In several cases fluid retention increased and hæmodilution occurred during the period of recumbency immediately before drainage was started (e g , cases 1 and 4, fig 3) This changing baseline is unimportant since a rapid reversal occurred when drainage was established

DURING DRAINAGE

Changes in the *blood electrolytes* during the drainage period are shown in table II and figs 1 and 2 An arbitrary period of 7 days is chosen for these results since the changes took place early in drainage but might be reversed when drainage was prolonged Cases 3a and 7 are not included, because treatment was changed during the period, but they showed similar changes It will be seen from table II that in most cases there was a rapid fall in plasma sodium, potassium, chloride, and bicarbonate concentrations, with a rise in blood-urea These changes in the electrolytes were greatest when drainage was brisk (fig 1, case 2) During more protracted drainage there was on occasion little change over several days, but, when the rate increased, a small loss of fluid was associated with a marked reduction in blood-electrolyte concentration (fig 1, case 4) The rough correlation of the fall in plasma-sodium and rise in blood-urea with the drainage-rate is shown in fig 2 Cases 2 and 6 with normal renal function differed in their behaviour from the rest since there was no immediate increase in blood-urea These two patients showed increasing uræmia later in drainage Salt supplements (cases 3 and 4) did not prevent a large fall in plasma-sodium concentration

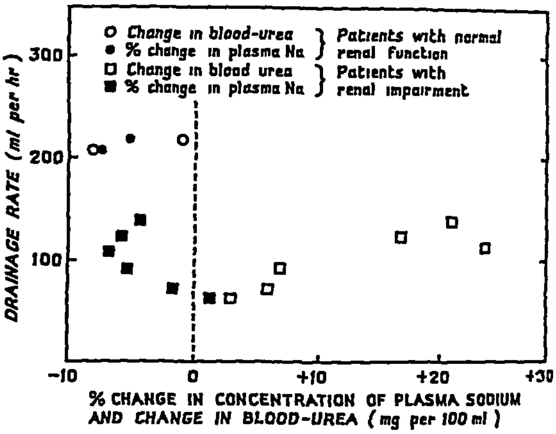

Fig 2—Changes in plasma sodium and blood-urea during the first 4 days of drainage related to drainage-rate

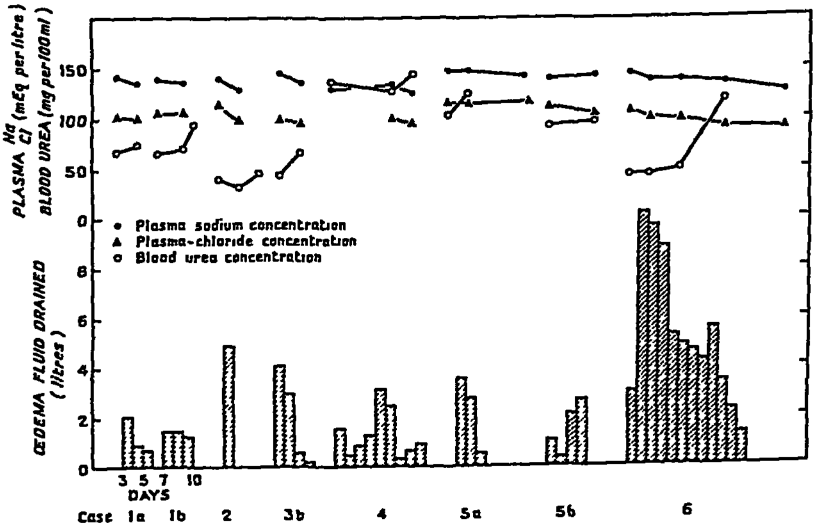

Fig 1—Chemical changes in plasma related to subcutaneous drainage The shaded blocks represent the drainage of œdema fluid

Total plasma-protein concentration rose in four instances during drainage (cases 1, 3, 4 and 6, table III and fig 3), this was largely due to increase in globulin and in one of these patients the albumin concentration fell These changes were accompanied by a rise in hæmatocrit In cases 6 and 7 the changes in the composition of the blood were extreme and led to circulatory collapse In case 6 drainage of nearly 66 litres over 17 days led to loss of 9 st. in weight The plasma-sodium fell progressively to 126 mEq per litre (fig 3) and a rapid rise in blood-urea was associated with severe oliguria At the same time the plasma-protein level rose by 30% In case 7 mercurial diuretics had been combined with a low-sodium diet for 3 months before drainage Removal of 7 litres over 6 days led to a fall in plasma-sodium to 126 mEq per litre and the blood-urea rose rapidly from 33 to 75 mg per 100 ml In both these patients nausea or vomiting, postural fainting, and hypotension developed Salt administration produced a prompt improvement with rise in blood-pressure, case 6 recovered but there was only a temporary response in case 7 who became anuric and died. In cases 2, 3b, and 4 there were similar but less severe symptoms, including nausea and hypotension, coinciding with the fall in plasma-sodium In case 4 venous engorgement due to heart-failure was present, but at the height of drainage the veins were so collapsed that venepuncture was difficult Cases 2 and 5 showed a different pattern of response to drainage Case 2 was anomalous since a sudden fall in plasma-proteins was apparently associated with a rise in hæmatocrit This is unexplained and may be due to an error

TABLE II—CHANGES IN PLASMA AND URINE ELECTROLYTES DURING THE FIRST 7 DAYS OF DRAINAGE

(The urine sodium figures are differences between the averages of 2 adjacent days before and 2 after the onset of drainage)

Case	Plasma					Urine sodium changes (mEq per day)
	Na (mEq per l)	K (mEq per l)	Cl (mEq per l)	HCO_3 (mEq per l)	Urea (mg per 100 ml)	
1a	−8 (−6%)	−0 5 (−13%)	−2 (−2%)	−4 (−13%)	+29	−2 5 (−29%)
1b	−2 (−1 5%)	−0 5 (−10%)	+1 (+1%)	−3 (−12%)	+6	
2	−11 (−8%)	−0 3 (−6%)	−14 (−12%)	−3 (−18%)	−8	−24 (−44%)
3b	−10 (−7%)	−0 3 (−5%)	−2 (−2%)	+1 (+4%)	+24	−13 (−57%)
4	−3 (−12%)	+0 1 (+2%)	−3 (−3%)	−1 3 (−7%)	+17	
5a	−6 (−4%)				+21	−9 (−50%)
5b	+2 (+1 5%)		−8 (−7%)		+3	−1 7 (−23%)
6	−8 (−5%)	−0 6 (−14%)	−10 (−9%)	+3 (+12%)	+3	

of determination In case 5 total plasma-protein and hæmatocrit fell during both drainage periods This case was exceptional in other respects Gross heart-failure was present and the fall in plasma-electrolyte concentrations described above was absent Moreover the rise in blood-urea was associated with a steep reduction in creatinine clearance The significance of these findings will be discussed later

Changes in the *daily sodium excretion* are shown in table II In most cases reduction in plasma-sodium concentration was accompanied by a fall in sodium output below the existing low value Nevertheless the urine was concentrated to a remarkable degree Thus specific gravities (fig 3) were attained in excess of the patients' performance at any other time, and urea was in some cases excreted above the "maximum concentration" after 12 hours' water deprivation and a 15 g dose of urea In case 4, with marked renal failure, the urine specific gravity exceeded 1 020 In most patients there was transient oliguria during rapid drainage, but subsequently the daily volumes of urine were greater than before drainage (fig 3), nevertheless high urine concentrations were maintained to the end of the period Patients with a free water allowance increased their intake and thirst was a frequent complaint

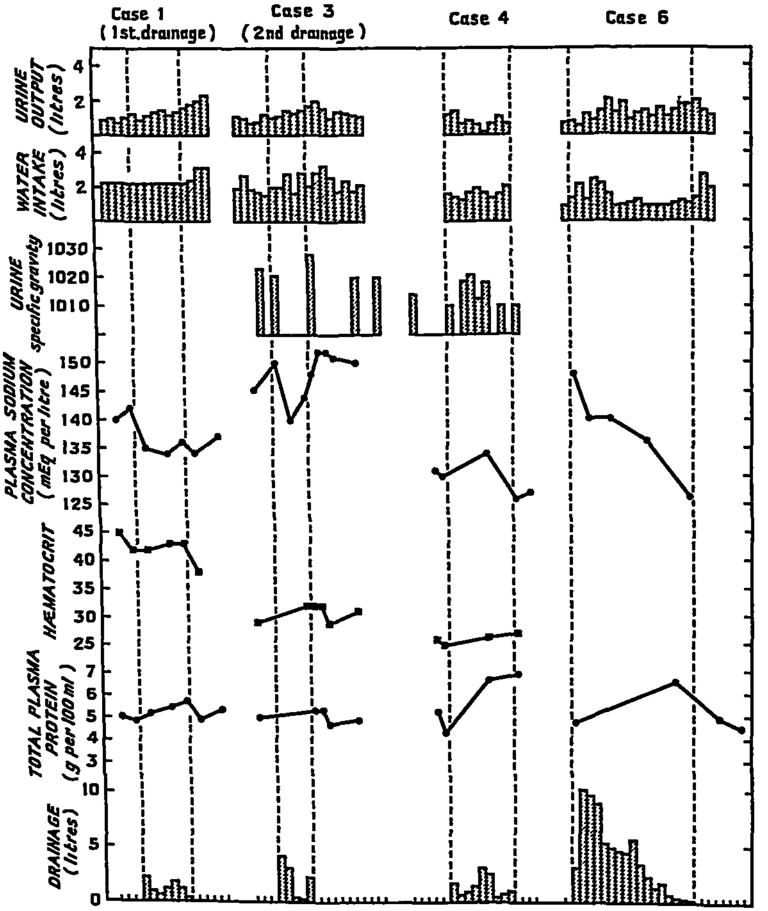

Fig 3—Relation of plasma volume to changes in plasma and urine concentration and water intake

Prolonged Drainage

After the early stages, the above changes in plasma and urine composition continued to a greater or lesser extent according to the rate of drainage In particular the serum-potassium rose rapidly in all cases except one and was associated with a rising blood-urea (table IV) In cases 1a (fig 4) and 3b where repeated daily measurements were possible, a progressive fall in creatinine clearance was observed over the corresponding period, amounting to 11 5% and 31% of the initial levels respectively This fall in creatinine clearance was too large and persistent to be explained by incomplete urine collection A curious observation was the increase in urinary calcium excretion following drainage in case 2 (fig 9)

The changes in the initial stages of drainage may be summarised as a fall in concentration of all the plasma electrolytes with a reduction in urinary sodium loss below the already low excretions of the nephrotic syndrome The urine was concentrated beyond the patient's previous "maximum urine urea concentration" and specific gravity The blood-urea rose from the start, nevertheless the creatinine clearance increased in two cases (1a and 2) Despite the fall in plasma-electrolyte concentrations, the hæmatocrit and total plasma-proteins rose in several patients These metabolic changes were associated with thirst, nausea, postural fainting, and hypotension

Towards the end of drainage additional changes included increase in plasma-potassium which preceded the rise in plasma concentrations of other electrolytes, and in the one case where measurements were made a marked fall in creatinine clearance There was at the same time a sharp increase in blood-urea (case 1, fig 4) In two patients the metabolic disturbance resulted in circulatory collapse

AFTER DRAINAGE

Various types of behaviour were observed after drainage ceased, in part

TABLE III—CHANGES IN HÆMATOCRIT AND PLASMA-PROTEINS DURING THE FIRST 7 DAYS OF DRAINAGE

Case	Hæmatocrit %	Albumin (g per 100 ml)	Globulin (g per 100 ml)	Total proteins (g per 100 ml)
1a	+1 (+3%)	+0 5 (+30%)	+0 3 (+8%)	+0 8 (+16%)
2	+5 5 (+16%)	−1·0 (−31%)	−0 6 (−27%)	−1 6 (−30%)
3b	+3 (+9%)	−0 3 (−17%)	+1·0 (+37%)	+0 7 (+16%)
4	+2 (+8%)	+0 2 (+7%)	+0 8 (+50%)	+1·0 (+23%)
5a	−4 (−16%)	−0 2 (−7%)	−0 3 (−11%)	−0·5 (−9%)
5b		−0 3 (−10%)	+0 1 (+4%)	−0 2 (−4%)
6				+1 3 (+36%)

these were related to the events described above, but in addition large changes were associated with post-drainage diuresis In those instances where the plasma-protein and hæmatocrit had increased steadily, there was a rapid return to the previous levels shortly after the end of drainage (fig 3)

A diuresis was seen in cases 1a and 3a (fig 4) This started just before or soon after drainage ceased, and was accompanied by a further sharp fall in plasma-sodium The blood-urea rose and at the same time a small but consistent rise in creatinine clearance was observed, together with a heavy urinary loss of potassium, sodium, and chloride The urine specific gravity fell to 1 012 The hæmatocrit and plasma-protein and electrolyte levels, which had risen a little towards the end of drainage, suddenly fell (case 1a) The interpretation of these somewhat bizarre results will be discussed later Clinical symptoms of potassium depletion appeared in both cases after diuresis In case 1a, a mild respiratory infection developed after drainage ceased, the patient looked ill and vomited small amounts, his abdomen became distended, and only scanty gut sounds were heard Some degree of hypokalæmia had been present throughout the drainage (3 5–3 9 mEq per litre), but during diuresis urinary potassium loss continued at 60 to 70 mEq daily though his food intake was negligible The electrocardiogram showed low voltage with flattened S-T segments (fig 5a) He was given potassium chloride (1 g t d s) for 5 days and slowly recovered, the abdomen becoming less distended and the E C G improving (fig 5b) This was apparently due to correction of his potassium deficit judging by the sudden rise in plasma concentration and increasing urinary loss after 7 days on a normal diet and 2 days of potassium administration This correction was nevertheless incomplete since a later balance study showed considerable potassium deficiency A renal biopsy (fig 6) showed the changes described in chronic potassium depletion (Relman and Schwartz 1955) in addition to those of type-2 nephritis The tubules were affected by gross vacuolar changes almost occluding the lumen The other patient (3a) with potassium depletion became confused and incontinent after diuresis His mental state improved after heavy potassium medication and electrocardiographic changes were reversed, but the evidence that his deterioration was due to potassium depletion is less conclusive than in case 1a

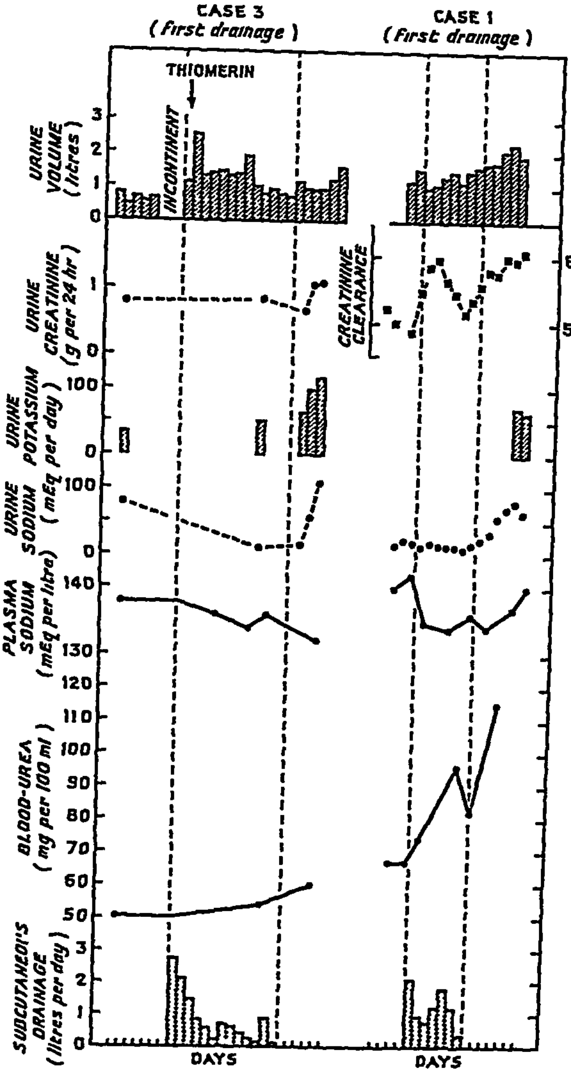

Fig 4—Diuresis after drainage in two cases

TABLE IV—PLASMA CHANGES LATE IN DRAINAGE THE NUMBERS REPRESENT CHANGES FROM THE PREVIOUS CONCENTRATION OF THE EARLY DRAINAGE PERIOD GIVEN IN PARENTHESES BELOW EACH FIGURE

Case	Na (mEq per l.)	K (mEq per l)	Urea (mg per 100 ml.)

6	−14 (*140*)	+1 8 (*4 6*)	−70 (*120*)
7	+4 (*126*)	+1 3 (*4 9*)	+42 (*33*)

Effects of Drainage on Renal Function

Changes in renal function were observed both during and after drainage Although some reference has already been made to individual tests, the results are best described over the whole period of observation Table I shows that initially the blood-urea was normal in three patients, slightly raised in two, and over 100 mg per 100 ml in two During drainage the blood-urea rose in every case (fig 1, tables II and IV) This nitrogen retention was associated with a fall in creatinine clearance towards the end of drainage in cases 1a, 5a and b, and 6 For example, in the latter case, renal function was initially normal but after drainage there was considerable deterioration (blood urea 195 mg per 100 ml , maximum urine-urea concentration 9 g per litre, creatinine clearance 25 ml per min) Peripheral circulatory failure was present in this case and all tests returned to normal following sodium administration

By contrast, in cases 1 and 2 renal impairment was prolonged, and appeared to be related to potassium depletion In case 1 a post-drainage diuresis led to acute-on-chronic potassium depletion and renal function tests improved after potassium administration (fig 7) At a later date advancing uræmia was not improved by potassium repletion, and was presumably due to progressive nephritis In case 2 there was no diuresis but impairment of renal function tests followed drainage Though there was inadequate information to diagnose potassium depletion, improvement in renal function followed treatment with katonium resin and potassium supplements

A third cause of uræmia appeared to be increased protein catabolism This is best illustrated by contrasting the renal function changes in cases 3b and 2 (fig 8) In case 3 the rise in blood-urea was accompanied by a fall in creatinine clearance and urea excretion consistent with circulatory uræmia as described above In fact the observed reduction in urea excretion completely accounts for the rise in blood-urea (assuming a total body water of about 60 litres) By contrast, in case 2, urea excretion rose during and after drainage at a time when the blood-urea was rising, excretion of ammonium, creatinine, and potassium increased concurrently (fig 9) A similar relationship was probable in case 1a, the blood-urea and creatinine clearance rising together during early drainage (fig 4)

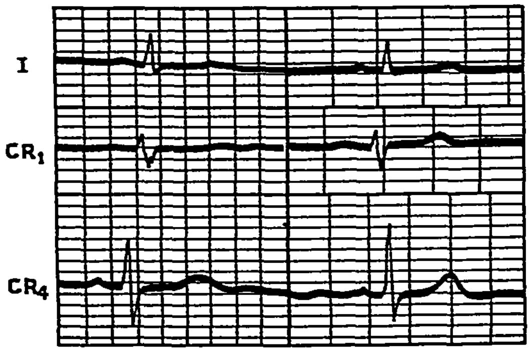

Fig 5—Electrocardiograms in case 1 (a) during potassium depletion, (b) during recovery following oral potassium therapy

Effects of Drainage on Protein Excretion

Studies of albumin excretion were made in case 1 and less complete observations in several others

Since urine protein is largely albumin, the daily protein excretion is related to the product of the mean plasma-albumin concentration and the glomerular filtration-rate Provided the plasma albumin/globulin ratio and glomerular permeability to protein do not alter, a graph plotted to show this relationship will be linear and there will be a negative intercept representing tubular protein reabsorption A departure from linearity may be due to a change in either glomerular permeability or tubular reabsorption of protein, although a more accurate measure of albumin clearance would be needed to identify the actual cause

The relationship of daily protein excretion to the product, plasma-albumin concention × 24-hour creatinine clearance, was investigated in case 1 The points obtained before and after drainage lie approximately on a straight line (fig 10), during drainage the relationship changed so that the points deviated in time sequence below the line,

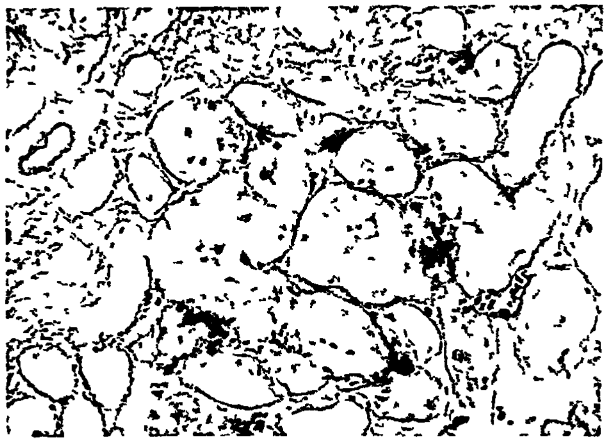

Fig 6—Photomicrograph of renal biopsy from case 1 during potassium depletion. (×180)

returning to it after drainage This fall in daily protein excretion was relative to all other factors—i e, it was independent of changes in the plasma-albumin concentration, plasma albumin/globulin ratio, or creatinine clearance, which might have been expected to produce it Similar results for protein excretion were obtained in case 2

Discussion

From the foregoing results it is apparent that several interrelated disorders may be precipitated by subcutaneous drainage These include peripheral circulatory failure, diuresis, potassium depletion, impaired renal function, increased urea production, and alteration in protein excretion

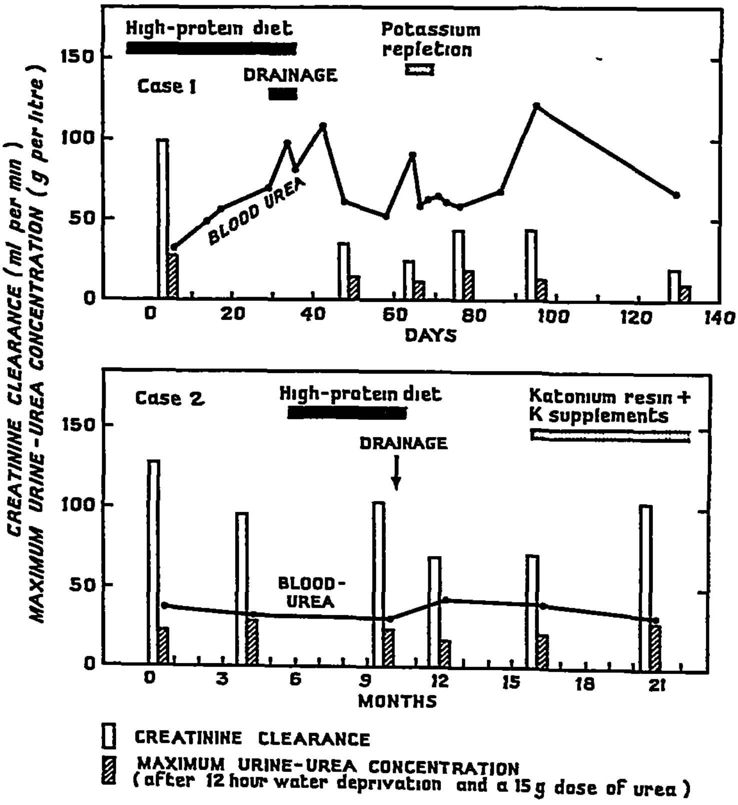

Fig 7—Renal function tests in two cases, related to subcutaneous drainage and potassium repletion

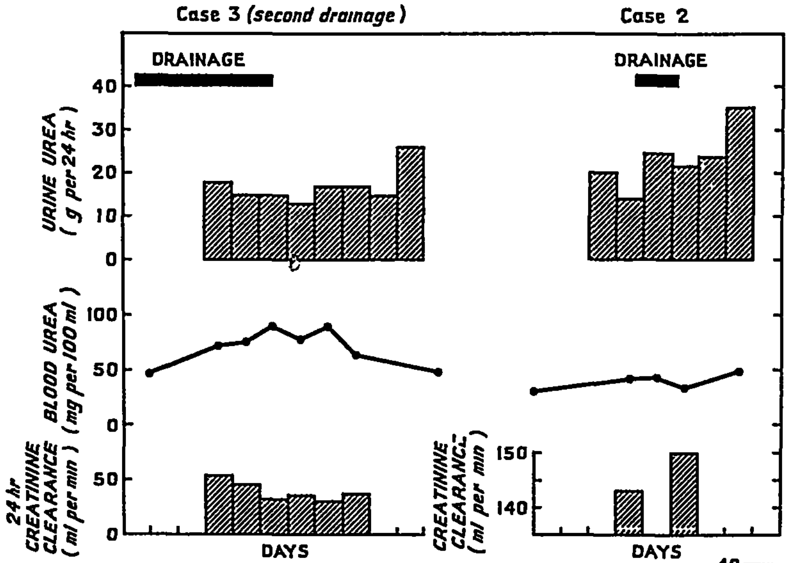

Fig 8—Factors contributing to uræmia

The two blocks representing creatinine clearance in case 2 are each the average of three measurements made over one-hour collection periods on the day concerned

In the early stages of drainage the biochemical disturbance consists of a fall in plasma-electrolyte concentration with a coincident reduction in sodium excretion This may be associated with a rise in hæmatocrit and total plasma-protein concentration The blood-urea rises yet the creatinine clearance and urine urea concentration may increase The patient experiences thirst as the plasma-electrolyte tonicity falls In terms of normal physiology these changes are mutually contradictory nevertheless similar observations have been made in a variety of pathological states, particularly the "reaction to injury" (Cuthbertson 1942, Eliel, Pearson, and White 1952, Wilson, Moore, and Jepson 1958)

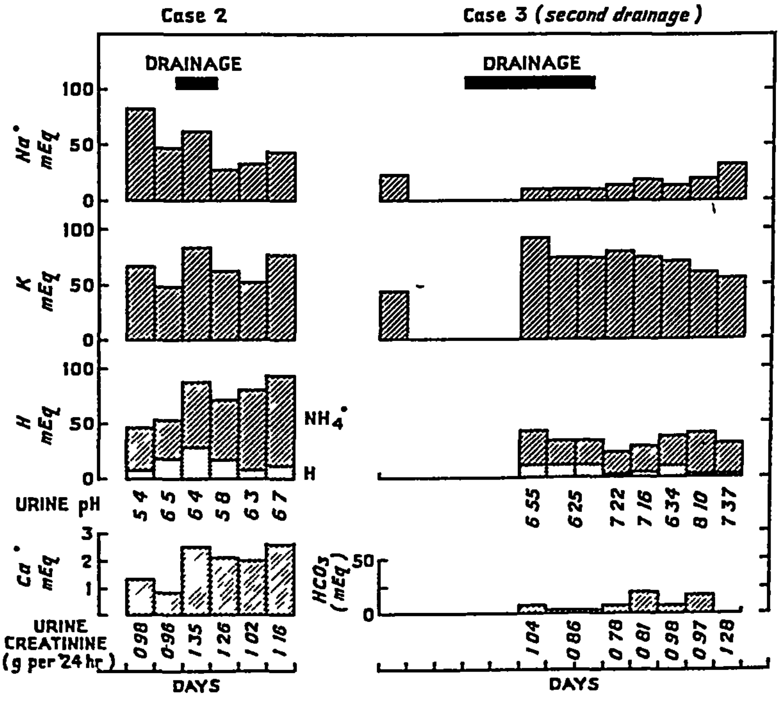

Fig 9—Daily urinary electrolyte excretion in two cases after drainage

The reaction-to-injury syndrome presents certain well-defined features—namely, hyponatræmia, oliguria with a concentrated urine, thirst, hypovolæmia, and increased protein catabolism—which may lead to uræmia and potassium depletion. The resemblance to the sequence of events associated with subcutaneous drainage is striking and has already been noted by Schaeffer (1955) and Roguska and Kishu (1957) There are certain differences In the reaction to injury the total plasma-protein level often falls—presumably an indication of the intensity of protein catabolism In our subjects a rise in total protein was observed, although this was often associated with a fall in albumin concentration Cuthbertson (1942) observed plasma-protein changes during the reaction to injury which were closely similar to our observations during œdema fluid drainage Davies et al (1959) have pointed out that albumin is probably a principal fuel in protein catabolism It is apparent that the change in total proteins will be the resultant of fluid-loss from the plasma and protein destruction In subcutaneous drainage, fluid-loss apparently predominates in many cases

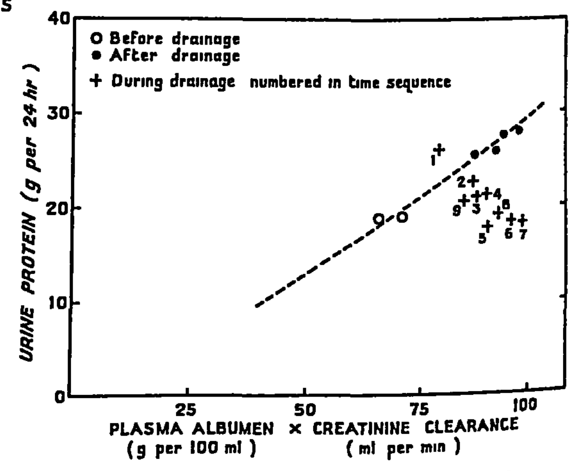

Fig 10—Protein excretion during drainage in case 1

It has been shown that certain of these biochemical abnormalities may already be present in the nephrotic syndrome before treatment is begun Thus the presence of increased protein catabolism is well established and may be associated with chronic potassium depletion (Fox and Slobody 1951) From our results it appears that subcutaneous drainage may provoke movements of tissue fluid and electrolytes which aggravate metabolic disturbances already in existence In this way a subclinical disorder may be made manifest by the appearance of symptoms of potassium depletion, circulatory collapse, thirst, or uræmia

One of the most contradictory aspects of the syndrome we have described is the association of thirst, hypovolæmia, and oliguria on the one hand with hyponatræmia on the other. We should expect the osmoreceptor thirst mechanism to be depressed when the plasma becomes hypotonic. Yet our two patients on a free water intake drank more, and those on a fixed water intake complained of thirst when the plasma-sodium fell during drainage. It is known that reduction in extracellular fluid volume from many causes may evoke thirst even when hyponatræmia is present (Peters 1952, Fourman 1959). However, thirst may occur with increasing œdema, and since the plasma volume has been shown to fall under these circumstances it is likely that hypovolæmia is the effective stimulus. It is of interest that in one patient (case 5 in our series) who was in gross cardiac failure, the plasma-proteins and hæmatocrit fell—i.e., the blood-volume increased during drainage. This patient was the only one in the series who failed to develop hyponatræmia. Roguska and Kishu (1957) also observed that during subcutaneous drainage patients with gross cardiac and renal failure behaved anomalously in that the plasma volume rose instead of falling.

Hypovolæmia may also be responsible for the oliguria. In the reaction to injury there is evidence that a fall in volume and tonicity of the plasma is accompanied by release of an antidiuretic substance (Le Quesne and Lewis 1953). A relation between plasma volume changes and antidiuretic activity has been shown in dogs by Henry and Pearce (1956) who obtained a diuresis in response to stretching of the left auricle and anti-diuresis when the plasma volume was reduced. This mechanism has been invoked to explain the paradox of oliguria in the presence of plasma hypotonicity, the assumption being that some prepotent stimulus to the posterior pituitary overrides the osmoreceptors. Further evidence for an antidiuretic factor is provided by our observation that during drainage several of our patients passed urine which was more concentrated (in terms of urea concentration of specific gravity) than was achieved after 12 hours' water deprivation, although this comparison would have been more conclusive had vasopressin been given during the latter test. Our results show, moreover, that plasma hypotonicity cannot be explained by increased electrolyte excretion, for the reverse was always found.

There is, however, an alternative mechanism which can account, in whole or in part, for the association of plasma hypotonicity with oliguria, concentrated urine, and reduced sodium excretion. A fall in glomerular filtration-rate, as a result of which a reduced filtered load of sodium is delivered to the tubular cells, can produce these changes (del Greco and de Wardener 1956). This effect on sodium and water excretion may occur even before inulin and creatinine clearance tests show any change; thus Berliner and Davidson (1957) found in dogs that renal-artery constriction insufficient to affect inulin clearance could lead to the formation of hypertonic urine even when a water load was given. In several of our patients the creatinine clearance was unchanged early in drainage but fell later, and this alternative mechanism could well have been operative. In two other patients, however, the creatinine clearance rose in the early stages of drainage as the plasma concentration and urine excretion of sodium fell. Hence it seems probable that both the antidiuretic factor and reduced glomerular filtration may be operative at different stages of subcutaneous drainage. But in either case there is good reason to believe that reduction in plasma volume is the primary cause.

A prominent feature of the reaction to injury is enhanced protein catabolism. We have already mentioned the evidence for excessive protein breakdown in the nephrotic syndrome. The results obtained during subcutaneous drainage indicate an aggravation of this process. Thus cases 1 and 2 showed a rising blood-urea with increasing creatinine clearance, and in case 2 this was accompanied by increase in excretion of urea, ammonium, and creatinine. The urine potassium loss rose concurrently (fig. 9). Nitrogen excreted in excess of the control level was about 13 g. in 4 days, equivalent to some 80 g. protein, which would be expected to release approximately 35 mEq. of potassium if the cells were normal. The observed excess excretion of potassium over 4 days was 48 mEq., giving a urine potassium/nitrogen ratio for the excess losses of 3.7. This high ratio suggests that, after drainage, potassium was lost from the cells in excess of that derived from protein breakdown. This is a common observation in the reaction to injury. Furthermore, protein catabolism by releasing water may be partly responsible for the hyponatræmia. Nevertheless the reduction in plasma-sodium concentration is more than can be accounted for by a combination of this factor and retention of water due to oliguria. This was confirmed by calculation from the balance data in cases 2 and 3b. It has been suggested therefore that excessive oxidation of fat may provide the additional water necessary to account for the observed plasma hypotonicity (Wilson, Moore, and Jepson 1958). An alternative explanation is the passage of sodium into the cells consequent on migration of potassium outwards. Evidence for this in gross œdema has been found by Laragh (1954) and it has been shown that chronic potassium depletion is a prominent feature of œdema states (Cort and Matthews 1954). Thus both the hyponatræmia and potassium depletion observed during subcutaneous drainage cannot wholly be explained by protein breakdown but involve some disorder of cell-membrane permeability to electrolytes.

In the preceding paragraphs we have suggested that changes in the blood and urine during drainage might be caused by hypovolæmia, either through the production of an antidiuretic factor or due to reduced glomerular filtration. There is another mechanism by which hypovolæmia may augment potassium excretion with sodium retention. Bartter et al. (1956) showed that acute reduction in blood-volume was followed by a brisk increase in urinary aldosterone and this was aggravated by hypoproteinæmia. Secondary aldosteronism might thus account for the retention of sodium and loss of potassium in subcutaneous drainage. In cases 2 and 3b in the present series the changes in urine electrolytes during drainage were consistent with enhanced aldosterone activity; thus sodium excretion fell, potassium excretion rose, and the amount of hydrion excreted as ammonium increased (fig. 9). After drainage the changes in sodium and potassium excretion were reversed while the urine became more alkaline and in one case a small bicarbonate diuresis took place. The ammonium excretion continued to increase while hydrogen-ion loss fell acutely. Similarly in cases 1a and 3a a large diuresis immediately followed drainage, plasma-sodium fell as plasma-potassium rose, there was a marked sodium diuresis, and the urine sodium/potassium ratio rose steeply (fig. 4). The rapid fall in plasma-protein and hæmatocrit levels immediately following the end of drainage (fig. 3) indicate a sudden rise in plasma volume such as might provide a sufficient stimulus for suppression of aldosterone secretion.

It is possible also that hypovolæmia may contribute to increased protein catabolism From observations on patients after hæmorrhage, Flear and Clarke (1955) showed that protein breakdown was related to reduction in blood-volume and could be prevented by restoring the blood-volume by transfusion

Uræmia in this series was due to multiple factors, one of which is increased protein catabolism Schaeffer (1955) observed the development of uræmia during subcutaneous drainage and attributed it entirely to reduced glomerular filtration Whilst our results (fig 8) confirm that this was present in some cases, enhanced urea production must have contributed in others, since in these creatinine clearance did not fall (it even rose) although urea excretion increased during the period of rising blood-urea

The reaction to injury has often been ascribed to various factors connected with surgical operations such as emotion, drugs, or anæsthesia (Le Quesne and Lewis 1953) It has also been said that the reaction is harmless and transient (Wilson, Moore, and Jepson 1958) This may be true after surgery, owing to the limited duration of the trauma During drainage of œdema fluid, however, the reaction may both last longer and lead to more severe electrolyte disturbances Neither drugs nor anæsthesia operate in producing the " reaction to drainage " and it seems unlikely that emotion plays any part In addition the diuresis following drainage may cause severe acute electrolyte depletion It is true that isotonic fluid is removed, but it is incorrect to argue that no disturbance of electrolyte metabolism will result This has been emphasised by Grossman (1957) in his review of the metabolic consequences of removing isotonic fluid from the body

Our conclusion is therefore that hypovolæmia may be an important factor in producing the metabolic disturbances which may complicate subcutaneous drainage The question of how hypovolæmia develops naturally arises It is known that removal of extracellular fluid tends to lower plasma volume (Cizek et al 1951) The reason for this may be that reduction in tissue pressure due to drainage disturbs the equilibrium across the capillary membrane so that fluid passes from plasma to the tissues Central venous pressure was not measured in the present investigation, but a reduction was noticed during drainage in case 6, a patient with cardiac failure A fall in venous pressure during drainage has been observed (Schaeffer 1955), and was associated with increased plasma-proteins, hyponatræmia, renal water retention, and potassium depletion

The observation that protein excretion fell during drainage may be interpreted as further evidence of hypovolæmia A rise in venous pressure due to heart-failure or the lordotic posture increases protein excretion Moreover the results of albumin infusion provide evidence that changes in protein excretion correlate with variations in plasma volume and venous pressure (Gregoire et al 1958) This supports the view that the fall in protein clearance during subcutaneous drainage was secondary to a fall in plasma volume It is probable, however, that other factors influence protein excretion

Practical Implications

We may conclude that, though subcutaneous drainage is a very useful procedure for relieving œdema resistant to other treatment, it is not free from metabolic dangers These are largely due to the aggravating effect of drainage on disorders of function already present in the nephrotic syndrome Acute hypovolæmia is the main result Acute-on-chronic potassium depletion may occur, particularly when diuresis follows drainage Uræmia may follow anuria due to circulatory failure, more often the patient undergoes a transient metabolic disorder with impaired renal function from which a slow recovery is made It is easy to prevent these effects when their causes are understood Where serious hypovolæmia occurred in our cases, treatment with salt by mouth produced obvious improvement This does not necessarily mean that the patients were suffering from whole body-sodium depletion, but rather that their hyponatræmia was related to acute shifts of electrolyte and water within the body in response to hypovolæmia A sudden increase in salt intake would tend to produce a rapid increase in the extracellular-fluid volume, counteracting the effects of drainage Prevention of the severe metabolic changes would be preferable, for salt administration, while bringing transient relief, defeats the object of drainage The metabolic abnormalities appear to be related in degree to the speed of drainage, and a slow steady drainage, if necessary in two stages, seems to be the best way to avoid acute collapse However, a wide individual variation of susceptibility to these effects exists, and it is wise to take the blood-pressure twice daily and measure the plasma-sodium and hæmatocrit frequently, so that drainage may be stopped as soon as marked metabolic changes appear Nausea, thirst, and faintness are useful premonitory symptoms Drainage should not be undertaken if recent heavy treatment with diuretics has been used In view of the risk to potassium-depleted subjects it is wise to give oral potassium supplements, in doses which the patient's kidneys can handle safely, before, during, and after drainage As dangerous hyperkalæmia is a possibility if drainage causes renal impairment, the plasma-potassium level should be measured daily during drainage or diuresis if oral potassium has been prescribed

The changes in protein excretion and renal function accompanying drainage appear to be related entirely to the metabolic effects of fluid loss, particularly plasma-volume changes and potassium depletion These changes may cause confusion by suggesting an alteration in the activity of the nephritis when in fact they are due to reversible disorders of function It is, however, possible that, if these disorders of electrolyte metabolism are prolonged, irreversible renal damage may occur and the nephrotic syndrome may be aggravated

Summary

Ten instances of subcutaneous drainage of œdema fluid have been studied, nine in patients with glomerulonephritis

Drainage gives rise to *complex metabolic changes* which are largely an exaggeration of the features of the nephrotic syndrome They include circulatory collapse, acute potassium depletion, and uræmia Alterations in protein excretion also occur

The origin of these changes is discussed, evidence is presented that an acute reduction in plasma volume is their main cause, and a parallel is drawn with the changes in the " reaction to injury "

The dangers of drainage and the means of their prevention are described

We are indebted to Prof Clifford Wilson and Dr J M Ledingham for much helpful advice and criticism, to Dr R R Bomford for allowing us to publish data from one of his patients, and to Dr William Evans for the electrocardiograms Dr J Ross performed the renal biopsy Many of the biochemical estimations were made by the staff of the clinical laboratory, directed by Dr H B May It is a pleasure to acknowledge the help of the nursing staff and dietitians Mr John King kindly prepared the photomicrograph

Addendum

Since this was written two papers have appeared containing applications of the renal counter-current concentration theory (Levinsky et al 1959, Bricker et al 1960) They offer an interesting explanation for the observation of high urine concentration and pathological water retention during periods of reduced glomerular filtration

THERE are 22 pairs of autosomes in man, and it is possible that 22 syndromes of autosomal trisomy exist, some, however, may be incompatible with intra-uterine life Mongolism is due to trisomy of one of the smallest chrosomes (Lejeune et al 1959) and, as it seems reasonable to suppose that the larger the extra autosome the worse the disturbance, most other trisomic syndromes might be expected to be at least as severe In man such aberrations would probably lead to generalised disorders of shape and size and to multiple structural abnormalities rather than to a single localised deformity

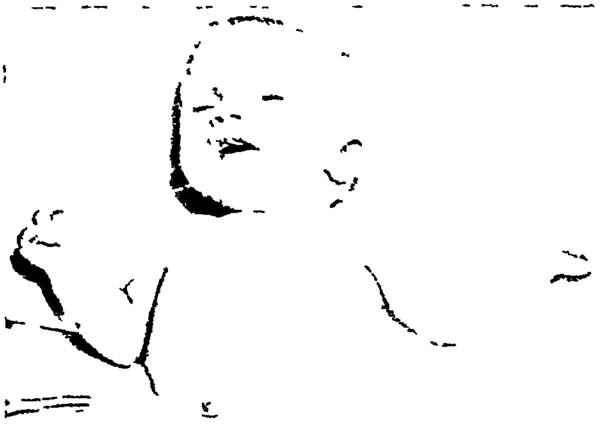

Fig 1—Appearance of the child showing triangular mouth, low-set ears, and position of hands

One such syndrome is, we believe, exemplified by the following case

Clinical Record

The infant, a girl, was delivered at term by cæsarean section (Mr G S Lester) at Marston Green Maternity Hospital on May 22, 1959

Her mother and father, aged 31 and 32 respectively, and her brother, aged 6, are healthy Between the births of her two children the mother had two miscarriages During this pregnancy hydramnios was suspected, and she had mild toxæmia Cæsarean section was carried out because of disproportion.

The birth weight was 5 lb 1 oz., length 17 in , head circumference 13$^{1}/_{2}$ in. Some unusual features were immediately obvious an odd-shaped head with wide occipitoparietal and narrow frontal diameters, a broad and flat bridge of the nose, low-set ears, a small mouth, inadequate for breast-feeding, webbed neck, hypermobility of the shoulders, so that they could almost be made to meet, and very short big toes with webbing between the 2nd and 3rd

On the second day a loud systolic murmur was noted, with its maximum intensity in the 4th left intercostal space near the sternum, the femoral pulses were normal During the first week of life she had several cyanotic attacks and transient jaundice, then her condition improved and after four weeks she was discharged At six weeks she again became jaundiced She was admitted to Little Bromwich Hospital and, after investigation had shown the jaundice to be obstructive, was transferred to the Children's Hospital, Birmingham.

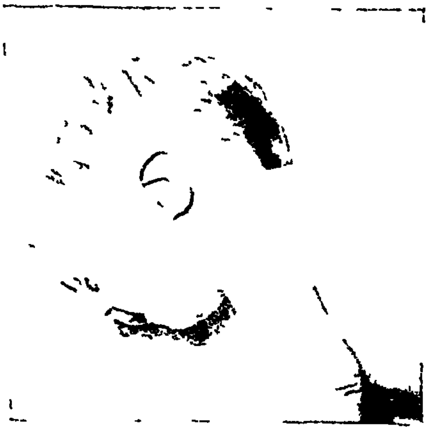

Fig 2—Photograph showing shape of head and of ears

She was then 9 weeks old and weighed only 6 lb 3 oz , length 19$^{1}/_{2}$ in., head circumference 14$^{1}/_{2}$ in. Some other features had now become obvious (figs 1 and 2)—a triangular mouth, a receding chin, and a wide-open metopic suture The ears were long and oblique, the main axis lying downwards, forwards, and inwards All the components of the ear were present, but their relative proportions were abnormal In particular there was an abnormally great distance between the crus antihelicis and the helix margin, giving the ear a pixie-look The chest was shield-like with nipples almost in the anterior axillary line, the fingers and toes were short and stubby with short irregular and flat nails, the fingers were tightly clenched though they could be straightened The carrying-angle of the elbow was normal and the external genitalia were normal The liver was enlarged The systolic blood-pressure was 130 mm Hg Mental development was retarded she did not smile, focus, or listen to voices

---

* Present address M.R.C Group for Research on the General Effects of Radiation, Department of Radiotherapy, Western General Hospital, Crewe Road, Edinburgh, 4

Investigations allowed us to rule out the following conditions as causes of the jaundice galactosæmia, syphilis, toxoplasmosis, Weil's disease, glandular fever, and hæmolytic disease of the newborn

Summary of Other Investigations

Urine—No inclusion bodies seen

Blood—White cells drumsticks present Group A Rh+ Haptoglobins type 2 2, transferrins type C

Buccal smear—Chromatin-positive

X-rays (R Astley)—On screening of the *chest*, the heart was seen to be moderately enlarged with a rather globular shape, some pulmonary plethora The descending aorta had an uneven contour in its upper part The appearances suggested left-to-right shunt *Skeleton* bone age normal, skull, clavicles, and cervical spine normal, thorax dome-shaped *Pelvis* iliac index normal according to the data of Caffey and Ross (1956)

Progress

The jaundice persisted, uninfluenced by a ten-day course of prednisolone After a needle biopsy of the liver (see below) an exploratory operation was performed by Mr Arnold Gourevitch, on Sept 21 the liver was greatly enlarged, the gallbladder was small and contained bile, the right, left, and common hepatic ducts and the common bile duct were present but very small The ovaries, fallopian tubes, and uterus were normal Cholecyst-jejunostomy was carried out and biopsy specimens obtained from the liver and right ovary After operation the jaundice deepened and bleeding occurred from the wound and into the bowel Despite repeated blood-transfusions the infant died on Oct 2

Pathological Findings

Liver Biopsy

The needle biopsy and that taken at laparotomy showed the appearances of giant-cell hepatitis (fig 3) The portal tracts and peripheral parts of the lobules were normal The central parts contained numerous bile thrombi and showed disorganisation with multinucleated giant cells and interstitial fibrosis

Biopsy of Right Ovary

Normal ovarian tissue with a normal complement of immature and maturing follicles

Necropsy

The external features have already been described

Hæmorrhage from the cholecystojejunal anastomosis filled the small and large intestine The mesentery was unfixed. The *liver* was firm, was considerably enlarged, and had a smooth external surface The cut surface was green and the lobular pattern accentuated The intrahepatic bileducts were not dilated The common bileduct was small in calibre but patent, and its mucosa was bilestained. The hepatic and cystic ducts were not dissected out, because of adhesions The *heart* weighed 41 5 g Both ventricles were hypertrophied and dilated and there was a high ventricular septal defect, 0 6 cm. in diameter The *ductus arteriosus* admitted the passage of a probe 2 mm in diameter The *left ovary* and the remaining part of the *right ovary* were normal The *spleen* was moderately enlarged, firm, and showed congestion of the pulp and slightly increased trabecular markings The *thymus* was markedly involuted and lay behind the innominate vein. The *skull* showed a patent metopic suture continuous with a wide anterior fontanelle The anterior third of the *falx cerebri* was narrow and did not extend for the normal distance into the longitudinal cerebral fissure The brain was slightly underweight (456 g) In both frontal lobes and the left parietal lobe the gyri were unusually prominent but not irregular, the sulci were wide and there was a moderate excess of subarachnoid fluid. The arachnoid, like the falx, did not penetrate deeply between the two frontal lobes but there was no abnormal continuity of cerebral tissue crossing the midline Slicing after fixation showed no further abnormality There was slight but definite *thoracic scoliosis* The *sternum* was thinner than normal and wide, and contained two long thin centres of ossification.

Histological examination of a portion of liver from near the hilum showed normal portal ducts and bileducts There was fibrosis in the centrilobular zones with considerable loss and disorganisation of liver cells Many were arranged in acinar groups Cells with three or four nuclei were common but there were few giant cells Three small extrahepatic bile ducts were seen in the hilar tissue One contained granular bile pigment

Cytological Examinations

Tissue specimens were removed during postmortem examination three hours after death These were collected in sterile Glaxo medium 199 and set up in tissue cultures twenty hours later using the method described by Harnden (1960) Samples of ovary and kidney proved to be infected and these were discarded but successful cultures were established from skin and muscle taken from the scapular region Cytological studies on the muscle culture were carried out ten days after the tissue was established in culture and on the skin culture after twenty-one days These showed that the great majority of cells from both cultures contained 47 chromosomes

Tissue	Chromosome counts						Sex chromosomes
	<45	45	46	47	48	>48	
Skin		1		22	3		XX
Muscle	1		2	35			XX

Counts other than 47 can probably all be attributed to technical errors such as breakage of cells during preparation Six cells from the muscle culture and five cells from the skin culture were carefully analysed and all showed that there were 5 chromosomes resembling pairs 17 and 18 (Ford et al 1958) of the normal complement in size and position of the centromere (fig 4) On the basis of examination of the analysed cells and of other cells not completely analysed, it was decided that there were 3 chromosomes indistinguishable from the no 17 chromosomes of the normal complement The most likely explanation for the defect is that the extra chromosome has arisen as a result of non-disjunction

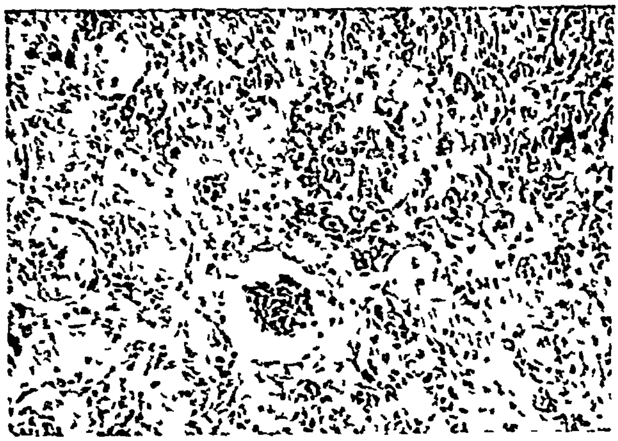

Fig 3—Low-power view of centrilobular zones of liver showing many multinucleated giant liver cells (Hæmatoxylin and eosin.)

during gametogenesis in one of the parents, and that the patient was therefore trisomic for the no 17 chromosome

Discussion

The main abnormalities were an odd-shaped skull, low-set and malformed ears, a triangular mouth with receding chin, webbing of the neck, a shield-like chest, short stubby fingers and toes with short nails, webbing of toes, ventricular septal defect, mental retardation, and neonatal hepatitis The presence of the hepatitis was probably fortuitous but the constellation of other abnormalities is consistent with the type of disorder to be expected from autosomal trisomy, and it seems likely that it may denote a clinical syndrome as specific as mongolism

The nomenclature and classification of syndromes in which multiple defects occur in association with webbing of the neck are confused, but it now seems possible that chromosomal studies of such cases will lead to clarification However, until agreement has been reached on a system of numbering or lettering the human chromosomes it would be premature to advance a new name for the syndrome described in this paper

In the meantime, we suggest that, of the several eponymous syndromes described, only the term "Turner's syndrome" (Turner 1938) should be retained, and that it should refer to females with varying degrees of gonadal dysgenesis and some of several associated abnormalities Of these, short stature, neck webbing, and cubitus valgus occur most commonly, lymphœdema of the extremities, congenital heart-disease, peculiar ears, renal anomalies, a shield-like chest, osteoporosis, and osteochondrosis of the spine, and many others, have also been described Most cases are chromatin-negative The majority so far examined have been shown to have an XO sex chromosomal constitution (Ford et al 1959, Fraccaro et al 1959) or are XO/XX mosaics (Ford 1959) Our patient with normal ovaries, normal sex chromatin, normal sex chromosomes, and an abnormal set of autosomes cannot be regarded as an example of this syndrome.

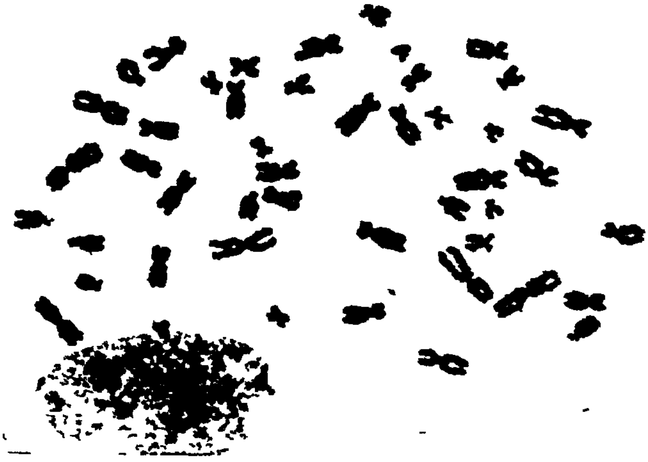

Fig 4—Chromosomes of cell (× approx. 800)

Some features of Turner's syndrome were included by Ullrich (1936) in his definition of the Bonnevie-Ullrich syndrome, and our case might be regarded as an example of the latter condition However, in later writings Ullrich (1938, 1949) has unfortunately so widened the scope of this syndrome, in which he now includes such diverse abnormalities as congenital amputations, hygroma, popliteal webbing, and agenesis of the cranial nerve nuclei, that the term lacks precision Another disadvantage inherent in its use is the eponymic implication that these conditions are analogous in their genesis to the familial anencephaly in the mouse which has been extensively studied by Bonnevie (1934) Further in the English-speaking countries the term Bonnevie-Ullrich syndrome is widely used as a synonym for Turner's syndrome (e g , Nelson 1959)

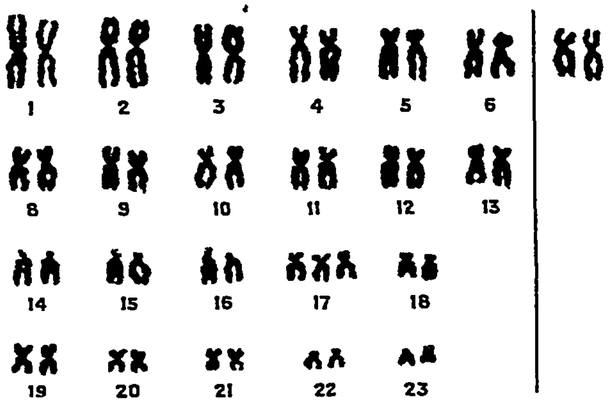

Fig 5—Chromosomes arranged in pairs

A few cases similar to the present one have been reported

Bizarro (1938) described a mentally defective boy with widespread abnormalities including webbing of the neck and low ears James (1952) described a mentally defective boy of 2 years, with low ears, webbing of the neck, slight webbing of the middle and ring fingers, inward curving of the little finger, and a loud systolic murmur The photograph shows short big toes Rossi and Caflisch (1951), classifying the various types of webbing, described, as an example of "status Ullrich bilateralis", a 12-year-old girl of short stature with webbing of neck, low-set malformed ears, a shield-like chest, and widely set eyes Puberal development was normal

These three cases and ours do not differ more from each other than would four arbitrarily selected mongols, and the possibility of chromosomal identity seems possible For further clarification it seems essential that other similar syndromes should, when possible, be described in association with chromosomal studies

It remains to be explained how some of the multiple abnormalities associated with an additional autosome in our case may also occur in association with a missing sex chromosome in Turner's syndrome

Summary

A female infant presenting with a peculiar facies, webbing of the neck, congenital heart-disease, neonatal hepatitis, and many minor abnormalities was found on postmortem chromosomal study to have an extra chromosome apparently identical to the 17th pair (Ford's nomenclature) This is the second condition of autosomal trisomy to be reported in man.

We are grateful to Dr C E Ford and Prof D H Hubble for much help with the preparation of this report, to Dr Elizabeth Robson for defining the haptoglobin and transferrin types, to Dr Sylvia Lawler for attempting to determine the blood-groups from an old specimen of blood taken before extensive transfusion, to Miss C. M. Scammell for technical assistance, to Mr D B Peakman for the photographs

SINCE the introduction of new methods which made possible the reliable determination of the chromosome number in man and the identification of individual chromosomes or at least groups of chromosomes, it has become evident that the presence of the normal complement of exactly 22 pairs of autosomes and 2 sex chromosomes is essential for normal development

Abnormal chromosome numbers are most likely to arise by non-disjunction in the first meiotic division Should this happen to the sex chromosomes in either parent, fertilisation will result in one of four abnormal sex-chromosome constitutions Of these possibilities one, YO, would unquestionably be lethal All of the remaining combinations have been observed XO, with a total of 45 chromosomes, causes gonadal dysgenesis (Ford, Jones, Polani, de Almeida, and Briggs 1959), and XXY chromatin-positive Klinefelter's syndrome (Jacobs and Strong 1959, Ford, Jones, Miller, Mittwoch, Penrose, Ridler, and Shapiro 1959) XXX results in disturbances (Jacobs, Baikie, Court Brown, MacGregor, Maclean, and Harnden 1959) that seem to indicate merely an œstrogen deficiency On genetical grounds it was not to be expected that the addition of an autosome to the normal complement would have a similarly restricted effect Only one type of autosomal trisomic has been reported to date, and although the extra chromosome is one of the two smallest autosomes of the haploid set, its presence in triplicate results in mongolism (Jacobs, Baikie, Court Brown, and Strong 1959, Lejeune, Turpin, and Gautier 1959)

It was to be expected that other autosomal trisomics, if they should be at all viable, would also display multiple congenital disturbances During a search among infants afflicted with such anomalies we have recently found two clinically similar cases, a boy and an unrelated girl, each with 47 chromosomes The syndrome is quite distinct from mongolism and includes anomalies of ears, hands, and feet, a small mandible, apparent mental retardation, spasticity, and a congenital heart defect The heart defect proved fatal at 2 and $2^1/_2$ months of age The cytological analysis is still in progress, it seems that the extra chromosome belongs to the E group (in our classification as proposed in fig 2) The present communication concerns a third type of autosomal trisomic which is distinct from mongolism as well as from the abovementioned syndrome

Clinical Data

The patient, a full-term female infant, was born in January, 1959, and is still alive (February, 1960)

This was her mother's first pregnancy Both parents are Caucasian, they were 25 years of age and in good health at the time of conception A survey of the parental family trees disclosed 3 first cousins, 7 aunts and uncles, and 31 great-aunts and great-uncles with no reported anomalies The parents had 89 first cousins, of whom 1 had a lumbar meningocele One of the patient's 88 second cousins has a clubfoot deformity, another a congenital shortness of one leg The grandparents are said to be normal Thus among 224 relatives of three generations only three anomalies were found, none similar to those observed in the patient

At 6 months' gestation the mother had an influenza like illness She received no X-ray exposure during the pregnancy and experienced no bleeding At birth, the patient weighed 6 lb 5 oz and was 19 in in length Intermittent cyanosis was noted in the first 3 postnatal hours and oxygen was administered in an incubator during the first 3 days No cyanosis has been observed since

The infant was first seen at the age of 1 month by one of us (D W S) She appeared to be a well-nourished infant with the following anomalies apparent anophthalmia, hare lip, cleft palate, and polydactyly of the left foot (fig 1) She weighed 7 lb 13 oz, was 21 0 in long, and had a head circumference of 14 25 in, and a chest circumference of 14 0 in, all of which are within the normal range The appearance of the external genitalia was that of a normal female infant

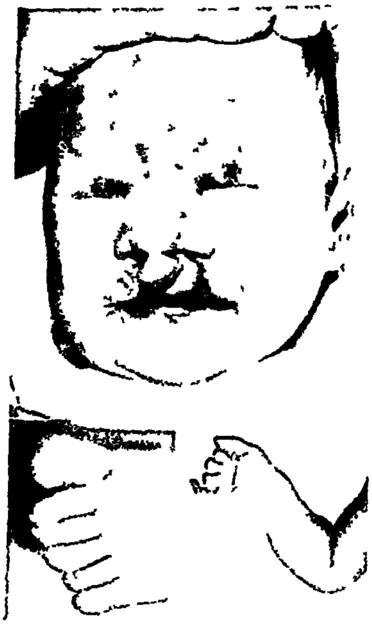

Fig 1—The patient.

The cranium was normal in size and contour and could not be transillumінated. Poor ossification of the cranial bones with wide membranous gaps between them was revealed by X-rays When the eyelids, which seemed to be normal, were pried open no organised ocular tissue could be seen or palpated The condition of the posterior orbit remains unknown as no biopsy was taken. The bilateral hare-lip deformity was worse on the right side The cleft in the palate was complete The left ear was smaller than the right In the 6th toe of the left foot X-rays disclosed normal phalanges based on a fully developed 6th metatarsal Both thumbs were maintained in a flexed position Upon their passive extension two small " clicks " were palpable at the metacarpal-phalangeal joint, an anomaly sometimes called " trigger thumb "

A grade-III rough systolic murmur was audible to the left of the sternum with maximal intensity over the 2nd to 3rd intercostal spaces The blood-pressure in the right arm was 120 90 mm Hg by flush technique and the pulse-rate was 120 Chest X-rays and fluoroscopy revealed a globular heart of

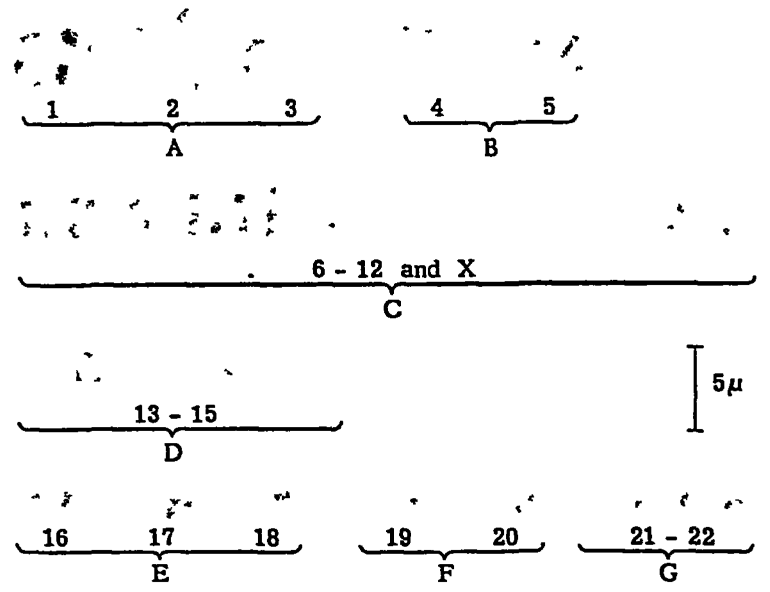

Fig 2—The 47 chromosomes of a cell from the bone-marrow of the right tibia. The D group contains 7 instead of, as normal, 6 autosomes.

normal size with the main mass of the heart projecting in a convex manner to the right. The aorta was seen to descend on the left. Pulmonary vascularity was increased. The electrocardiogram was interpreted as showing a vertical position with marked right axis deviation. The clinical impression was a rotational anomaly with intraventricular septal defect.

Non-elevated simple capillary hæmangiomata were present on the nasal bridge, both upper eyelids, the posterior neck, and scattered small areas on the forehead and lower back. A neurological study showed that the infant moved all extremities with fair muscular tone. The deep tendon reflexes were normal. A fair Moro reflex was elicited by sudden movement, but no such reaction was provoked by a loud sound. As the infant showed no response to sound she was considered to be deaf. In a subsequent evaluation at 5 months of age it was estimated that she performed at the developmental level of a 1-month-old. Since the age of 3 months she has had frequent brief seizures of myoclonic type.

Laboratory studies of urine and blood yielded normal values, as did measurements of the concentrations in the serum

CHROMOSOME COUNTS IN BONE-MARROW MITOSES

Specimen from	Chromosome number 44	45	46	47	48	49	Number of mitoses
Right tibia				4		1	5
Left ,,			1	6			7
Right ,,			2	37			39
Total			3	47		1	51

of CO_2, chloride, sodium, potassium, calcium, phosphorus, serum alkaline phosphatase, total protein, and fasting blood-sugar.

Particular attention was paid to the question whether the patient might be an atypical mongoloid. She does have simian creases in the palms of both hands, but in every other aspect of the physical evaluation she did not appear mongoloid. X-ray photographs of the pelvis were normal for her age. She lacked the hypotonia usually evident in an infant mongoloid. In addition, the skin patterns of the hands and feet render mongolism very unlikely. We are obliged to Dr Irene A. Uchida for a detailed analysis of these patterns. Their overall logarithmic index is −1·81, a value which is smaller than that found by Walker (1957) in all but 2 of 150 investigated mongoloids and which is well within the range of non-mongoloids. This index, in conjunction with the clinical picture, justifies the conclusion that the patient is not a mongoloid. It will be seen that the cytological analysis leads to the same conclusion.

Cytological Observations

The chromosomes were studied in cells from bone-marrow cultures. The culture technique followed was essentially that recommended by Ford, Jacobs, and Lajtha (1958).

Marrow specimens were obtained by aspiration first from the right tibia, later from the left tibia, and still later again from the right tibia. In the case of the first two specimens only the buffy layer of the centrifuged marrow was cultured in saline with AB serum from a blood-bank. The third specimen, without centrifugation, was put into a culture medium (about 0·25 ml. marrow per 4·0 ml medium) consisting of equal parts of Hanks' balanced saline (with antibiotics, adjusted to pH 7·4) and fat-free serum collected from an AB donor after fasting. The first two specimens yielded only a few countable mitoses, the third produced an abundance. Observations on bone-marrow from other individuals also suggest the last-described technique to be

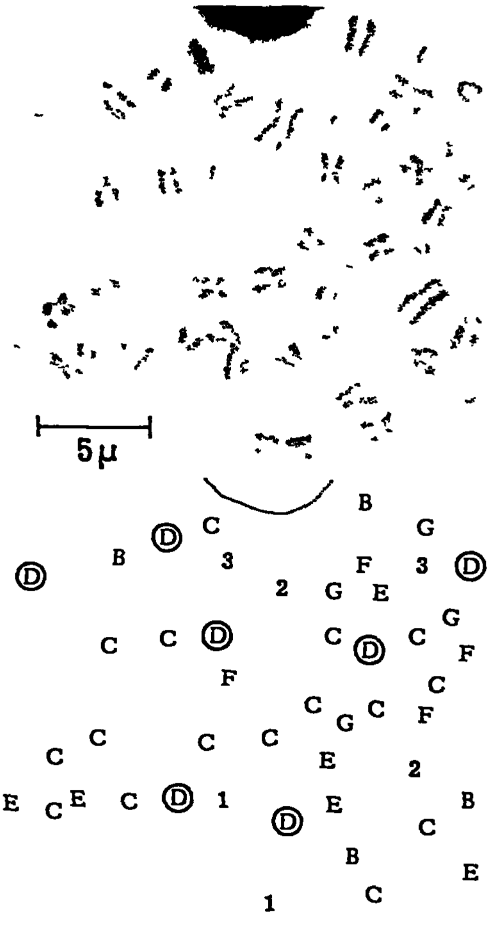

Fig 3—A cell with 47 chromosomes, including 7 of the D group, from the bone-marrow of the left tibia. The letters designate chromosome groups as in fig 2.

superior, but it, too, often fails to provide more than a few usable mitoses

The cultures, 4 ml aliquots in 25 ml screw-cap tubes, were kept for approximately 24 hours at room temperature, then for 5 hours in an incubator at 37°C, and after the addition of colchicine for 2 more hours in the incubator The colchicine concentration in the culture medium was 0 0001% Sodium citrate was used as by the above authors After fixation in 1 3 acetic alcohol, the material was either left in 75% alcohol in a refrigerator for future use or stained immediately by the usual Feulgen procedure The squashing was done in 45% acetic acid Thereafter the slides were either made semipermanent by surrounding the coverslips with Kroenig cement or mounted in 'Euparal' To that end the preparations were frozen on dry ice, the coverslips pried off, and the slides passed through 95% into absolute alcohol

Semipermanent slides have the advantage that microscopically controlled additional squashing can be applied This often renders the chromosomes countable in a cell that was not suitable before Even more important, sufficiently severe squashing tends to spread the chromatids of the smaller chromosomes in a horizontal plane, an almost necessary condition if the latter are to be reliably classified It matters little that squashing, when carried that far, may distort some of the larger chromosomes (see fig 2)

Chromosomes were counted for the record only when their arrangement suggested that none had been lost by over-squashing Absolute assurance on this point is impossible, indeed, in one instance of repeated squashing we observed a chromosome being expelled from a cell that continued to have an unbroken appearance However, such cases are evidently rare The outlay of the chromosomes of each cell judged to be acceptable in the above sense was first sketched The decision to count them for the record was made by two of us (K P and E T) who had both to be satisfied that the sketch contained no errors We refrained from any attempt to ascertain the chromosome number before this decision Thereafter the count obtained from the drawing was not open to further revision It is obviously impossible to estimate, without a deliberate count, the number of some 46 scattered chromosomes with any precision Therefore, the above procedure will ensure that, within the narrow range of chromosome numbers which are of any interest in the present context, subconscious bias can affect neither the selection of cells to be counted nor the counts themselves A very few cells with less, mostly much less, than 44 chromosomes were discarded, as were polyploid mitoses which seem to occur in every bone-marrow

It is evident from the table that the basic chromosome number of the patient is 47 As this number predominates in the marrow of both tibias the possibility of mosaicism can be dismissed The few cases with numbers other than 47 may have come about in part by loss of chromosomes during preparation, in part by counting errors, but we would not rule out the possibility of having encountered an occasional cell with an atypical chromosome complement

There was no lack of cells in which all chromosomes or major groups of them could be analysed In all suitable cells with 47 chromosomes an apparently entirely normal female complement was found, including 4 small chromosomes (group G in fig 2) and 16 of the group to which the X chromosomes belong (group C in fig 2) The presence of two X chromosomes was further borne out by buccal smears, fixed and stained with acetic orcein, in which 25 out of 100 nuclei were chromatin-positive The extra chromosome belongs to the group of medium-sized acrocentric autosomes (D in fig 2) In at least five cells all 7 D chromosomes were about as clear as in fig 2, each showing the very small short arm characteristic for this group There were, of course, still other cells—e g, that of fig 3, in which all 7 D chromosomes could be identified

We cannot say to which of the three pairs of the D group the extra chromosome belongs, the reason being that we cannot identify the individual pairs It will be pointed out elsewhere that the "pairing-off" of chromosomes by size in the case of this, as of certain other groups, is almost meaningless because it neglects the not at all negligible random variation of the apparent chromosome length One of the D pairs has a minute satellite (Tjio and Puck 1958, Chu and Giles 1959) We have seen it, but too infrequently—even in orcein slides made for this purpose—to have much hope that the presence or absence of a satellite at the extra chromosome could be established with the present technique

Discussion

It will, we presume, not be doubted that the observed abnormality of the chromosome complement is the cause of the clinical anomalies, but the question could be raised whether the extra chromosome might not be a translocation chromosome which merely happens to have the size and shape of a D chromosome If so, the chromosome piece actually duplicated could be considerably shorter than a whole D chromosome Suffice it to say that for various reasons we consider this unlikely in the present case and that we are confident future findings will confirm the extra chromosome to be a genuine D chromosome. If it is, the present combination of a specific cytological situation with a certain pattern of anomalies is bound to be encountered again In independent cases of translocation a similar clinical pattern might reoccur but would not consistently coincide with the presence of an extra chromosome of the D type

Trisomy no doubt always has its origin in non-disjunction The latter represents, if the original chromosome complement is structurally homozygous, a meiotic or (more rarely) a mitotic malfunction Such an accident can involve any chromosome, even though some chromosomes may be much more prone to it than others, depending on their length and centromere position We suspect that non-disjunction occurs occasionally in the healthiest of tissues The frequency of this as of any malfunction is, however, apt to be influenced by genetical and environmental factors One need not be surprised that there is a correlation between the incidence of mongolism, now understood to result from non-disjunction, and the age of the mother, which, after all, is to the oocyte an environmental factor This strong positive correlation is not likely to be restricted to one particular chromosome In consequence, we should expect that the frequency of trisomics other than mongoloids will also be found to increase with the age of the mother This appears to be the case Out of four such trisomics observed so far only the present patient has a young mother The mothers of the two autosomal trisomics of another type that had been mentioned in the introduction were both about 46 years of age at the time of conception The mother of the XXX female reported by Jacobs, Baikie, Court Brown, MacGregor, Maclean, and Harnden (1959) was 41 years of age at conception These are not likely to be mere coincidences

Of the 22 conceivably viable types of autosomal trisomics three have been found so far How many more are viable is not known, but it seems certain that not all of them are As each of the viable ones will probably show a clinically distinguishable syndrome, we may expect that an ætiologically unique group of a limited number of " autosomal trisomy syndromes " will become established To the human geneticist these will be of continuing interest, he will in particular look forward to cases in which the presence of known genes in the parents can be related to peculiarities in the trisomic child It seems likely that every component anomaly of a trisomy syndrome reflects, by way of a dose effect of gene action, the presence in the respective chromosomes of at least one gene locus that plays a prominent role in the normal development of the afflicted organ, indeed, we suspect that many of the trisomy anomalies can also be produced individually in euploid persons by the heterozygous or homozygous presence of a suitable mutated allele of the responsible gene Polydactyly and hare lip with cleft palate in the present patient may be cases in point These also suggest that trisomy may become instrumental in establishing for the first time autosomal linkage groups in man

Summary

The patient, a girl infant, has 47 chromosomes, the extra chromosome being one of the medium-sized acrocentric autosomes

The presence of this extra chromosome is regarded as the cause of the following observed combination of congenital anomalies

Cerebral defect	Simian creases
Apparent anophthalmia	" Trigger thumbs "
Cleft palate	Polydactyly
Hare lip	Capillary hæmangiomata

Heart defect

We wish to thank Mr H Montague and Mr J Tiedt from the photographic laboratory for technical assistance.

The work has been supported in part by a grant from the U S Public Health Service (C-3313) and by an institutional grant from the American Cancer Society, Inc.

Addendum

Since this report was written, another patient, an unrelated female infant, has been found to combine a similar set of congenital anomalies with possession of an extra D chromosome which no doubt is the same as the one in the present case

" Salesmanship includes the art of displaying small assets in a convincing way The late Lord Duveen (who made a fortune by selling pictures) possessed this gift When he took his small daughter to the sea-side for the first time he exhorted her to paddle She put one toe in the sea, said it was too cold, and refused to try any more. Lord Duveen gathered some driftwood and lit a fire He filled the child's bucket with sea water and heated it till it was nearly boiling Then he emptied the steaming liquid into the vast cold sea 'Go on, try again now,' he urged her She cautiously tried one toe 'Oh, thank you That's much better,' she said, and paddled happily for the rest of the afternoon The results of pharmacological treatment mostly depend upon similar salesmanship by the doctor "

From the University Department of Medicine and a Surgical Unit, Manchester Royal Infirmary

It has long been known that children with chronic uræmia may develop a form of rickets, and it has been realised more recently that uræmic adults sometimes develop florid osteomalacia (Stanbury 1957) These disorders can be corrected by vitamin D which, given in high dosage, promotes the intestinal absorption and bodily retention of calcium and phosphorus (Stanbury and Lumb 1959) In patients with azotæmic rickets or osteomalacia one can usually find also histological (Follis and Jackson 1943, Berner 1944, Ball 1959) and frequently radiographic evidence of osteitis fibrosa which, in agreement with Gilmour (1947), we believe to result from secondary hyperfunction of the parathyroid glands As the rickets or osteomalacia heals during treatment with vitamin D, the accompanying radiographic changes of secondary hyperparathyroidism disappear, and it seems likely that treatment causes involution of the hyperplastic parathyroid glands (Stanbury and Lumb 1959) In exceptional patients with chronic uræmia, osteitis fibrosa is the dominant or only osseous lesion and the clinical, pathological, and radiographic features may then be indistinguishable from those of primary hyperparathyroidism At necropsy in such cases it is usual to find massive enlargement of the parathyroid glands, and the condition might reasonably be classified as uræmic or azotæmic hyperparathyroidism In azotæmic hyperparathyroidism as thus defined, the serum-phosphate is always high and the serum-calcium is commonly normal (Shelling and Remsen 1935, Magnus and Scott 1936, Dreskin and Fox 1950) or even elevated (Hubbard and Wentworth 1921, Herbert et al 1941, Richards 1951, Brookfield et al 1955-56) Since effective doses of vitamin D might be expected to increase the serum levels further, its use in these patients would carry a grave risk of induced metastatic calcification—a complication to which as a group they are especially liable (Herbert et al 1941) Moreover, previous experience suggests that therapy with vitamin D cannot be relied on to cause involution of the grossly enlarged and possibly autonomous parathyroid glands in this syndrome (Stanbury 1957) If it is decided to treat a patient of this group, the only logical thing to do is subtotal parathyroidectomy This should correct the osteitis fibrosa, leaving a residual osteomalacia, which might then be expected to respond to the large doses of vitamin D required in the uræmic state

This communication describes the case of a chronically uræmic patient on whom we performed subtotal parathyroidectomy in a successful attempt to relieve severely painful osseous disease. Our experience of parathyroidectomy in primary hyperparathyroidism with severe renal damage (Nicholson and Stanbury 1960) and of corrective orthopædic surgery in azotæmic renal rickets (Stanbury and Lumb 1959) convinced us that the operative hazard could be safely met

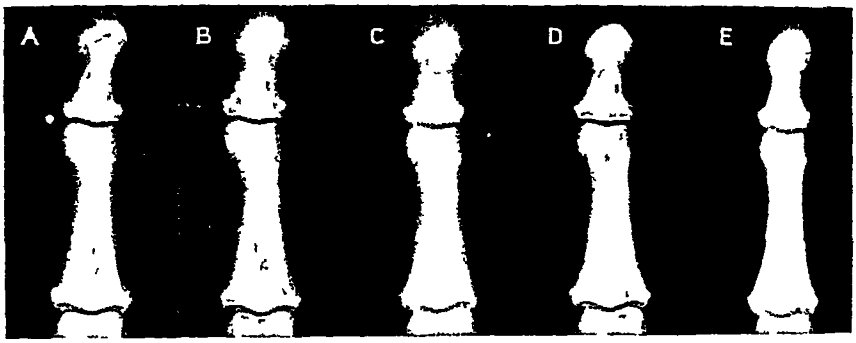

Fig 2—Radiographs of the same finger, taken preoperatively and on the 16th, 40th, 120th, and 170th days after operation

Minor improvement in the radiographic appearance of the second finger may have been due to deposition of intravenously administered calcium No really significant improvement took place until effective therapy with vitamin D (6 25 mg per day) was started on the 87th day after operation (D and E in the series)

Case-report

The patient, a single woman aged 33, attended the County Hospital, Lincoln, in October, 1957 She was complaining of lack of energy and of severe pain in the shoulders, back, knees, and ankles Some ten years earlier she had found herself unusually tired and, at the age of 26 years, her shoulders had begun to ache This aching worsened and spread insidiously to involve other areas, during the two years before she attended hospital pain was almost constant Her walking became slow, painful, and waddling, she was unable to kneel or to climb stairs without experiencing intense pain in the knees and thighs She developed curvature of the upper thoracic spine and lost height

She had no urinary symptoms other than a distended bladder on waking in the morning, and there was no history of acquired renal disease She had, however, needed to drink large volumes of water for as long as she could remember—certainly since childhood In view of the possibility that her polyuria and polydipsia were caused by some congenital renal anomaly, it may be relevant that a sister, 2 years younger than the patient, is known to have renal disease with azotæmia and normal blood-pressure This sister has always been regarded as an invalid and has suffered recurrent urinary infection her blood-urea has varied from 50 to 150 mg per 100 ml. and on one occasion the urea clearance was 24% of normal intravenous pyelography revealed no anatomical abnormality and there was no radiographic evidence of hyperparathyroidism (Dr E P Morley)

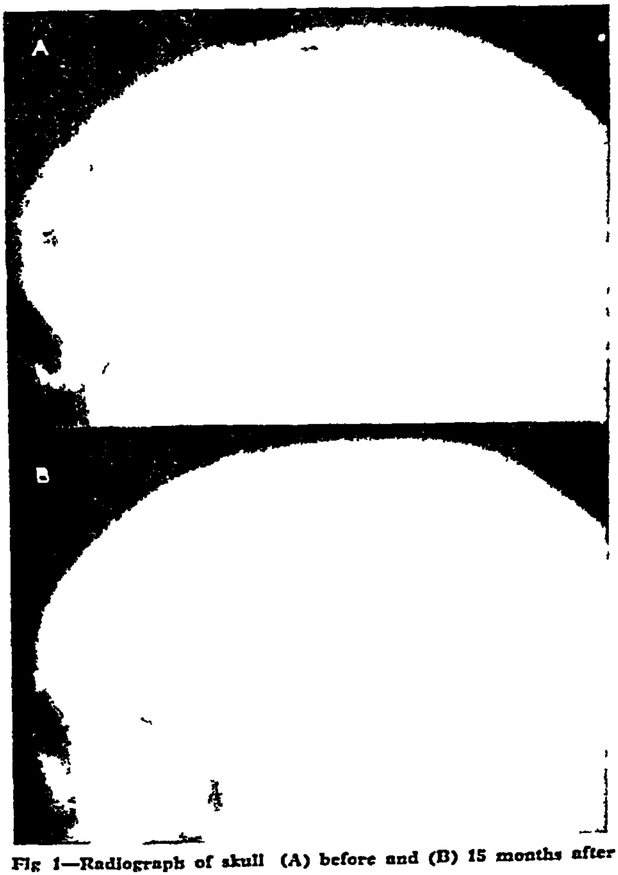

Fig 1—Radiograph of skull (A) before and (B) 15 months after operation

Examination

On examination (May, 1958) the patient had the appearance of chronic uræmia with a sallow complexion and anæmia (Hb 9 2 g per 100 ml) The blood-pressure was 140/85 mm. Hg There was a smooth kyphosis involving the upper dorsal spine but no other deformity She walked very slowly with a characteristic waddle, abduction of the shoulders was painful as were attempts at climbing stairs Even at rest in bed her knees were painful, and holding her arms forward when knitting caused pain to extend down the arms from the outer end of the clavicles The bones of the leg and of the forearms were tender on manual compression

Investigations

Radiographic survey of the skeleton showed a gross degree of the changes usually associated with hyperparathyroidism but no specific evidence of osteomalacia The skull was granular (fig 1) and the vertebral bodies in the thoracic and lumbar regions showed typical banded sclerosis, some of the thoracic vertebral bodies were partially collapsed The digital phalanges showed extensive scalloped erosions of the cortex (fig 2), and typical cortical erosions were also present at the upper ends of both tibiæ and under the outer third of the clavicles There were subarticular erosions, such as we see in either primary or secondary hyperparathyroidism (Popert and Stanbury 1960), involving the sacroiliac and acromioclavicular joints and the symphysis pubis There was light tubular calcification in the lower parts of the anterior and posterior tibial arteries Tomography of the renal areas revealed no evidence of metastatic calcification, and the kidneys were of approximately normal size and outline

A biopsy specimen of sternal bone was taken at Lincoln, and the decalcified section was reported on by Dr J Ball as follows “ There is gross but patchy osteitis fibrosa and increased osteoclastic resorption, there is also considerable osteoblastic activity The picture is compatible either with primary hyperparathyroidism or with advanced secondary hyperparathyroidism ”

The urine contained moderate amounts of protein but no formed elements The serum-urea was 180 mg per 100 ml., the serum-calcium, 8 8 mg per 100 ml , the serum-phosphate, 6 5 mg per 100 ml , and the serum-alkaline-phosphatase 75 King-Armstrong units per 100 ml Because the patient would not at first take adequate amounts of water and salt, the serum-urea rose rapidly to 265 mg per 100 ml and the serum-phosphate to 8 5 mg per 100 ml , but these changes were reversed by enforced hydration

* Operation was on day 40. Thereafter administration of sodium bicarbonate 4 g. daily was continued.

Metabolic balances were determined by conventional techniques. Frequent chemical analyses were made of replicate diets and any dietary rejects were analysed. The figures in parentheses, in the column showing phosphorus balance data, refer to the 'theoretical phosphorus balance' calculated from the observed calcium and nitrogen balances according to Reifenstein et al. (1945). Note that the observed and theoretical P balances were virtually identical except in period D.

Operation

It was considered that the patient had severe secondary hyperparathyroidism, and that the further unpleasant complication of gross metastatic calcification was probably imminent. In view of this expectation and her miserably painful state we decided on parathyroidectomy. On June 30, 1958, the neck was explored and five parathyroid glands were identified, the fifth being situated at the site of left upper pole of the thymus. A total of 3·59 g. of parathyroid tissue ("thymic", 1·05 g.; left lower, 0·83 g.; left upper, 0·21 g.; right lower, 1·0 g.; right upper [part], 0·5 g.) was removed, an estimated 0·2–0·3 g. of the right upper gland was left intact. All removed glands were similar in appearance; they were firm, and the cut surface was greyish-white in colour. All had similar histological appearances. The hyperplastic tissue consisted mainly of chief cells which showed a good deal of vacuolation in transition to water-clear cells. There were numerous circumscribed masses of oxyphil cells. Each gland contained nodular areas of acinar formation consisting of either oxyphil or vacuolated cells; some of these nodules (1–2 mm. in diameter) were visible to the naked eye in the stained sections.

METABOLIC INVESTIGATIONS

Metabolic Balances before Operation (see table, periods A and B)

The fæcal output of calcium was consistently higher than the dietary intake and the calcium balance was negative. The ratio of fæcal to urinary phosphorus was increased. These findings are characteristic of the uræmic state; they differ slightly but significantly from our findings in uræmic rickets or osteomalacia, wherein the urinary calcium is commonly 40 mg. per day or less and generally a smaller proportion of the dietary phosphorus appears in the urine. These differences are readily explained by the normal calcium and elevated phosphate levels in the patient's serum.

Administration of sodium bicarbonate (4 g. per day) had no net effect on the external mineral balances (see table), even though it produced a progressive fall in the serum-urea and apparently corrected the metabolic acidosis (fig. 3). (The association of a positive nitrogen balance with *falling* serum levels of urea [see table] is a common finding in our metabolic studies of uræmia.)

Effects of Parathyroidectomy

The biochemical changes in the serum are charted in fig. 3. The further fall in serum-urea during the few days after operation we ascribe to a negligible intake of protein coupled with continued intravenous administration of saline fluids. The serum-calcium fell from 9 to 7·2 mg. per 100 ml. within 6 hours and to 5 mg. per 100 ml. by 50 hours; it remained close to the latter value during the next 20 days, despite daily intravenous injections of calcium gluconate. The serum-inorganic phosphorus fell more slowly to a level of 3·3 mg. per 100 ml. (fig. 3).

The hypocalcæmia was associated with severe sensory and motor tetany and with an unpleasant sense of bodily cold. When tetany was most severe, the patient complained of blurring of vision and difficulty in accommodation; this remains unexplained.

The patient's osseous pain remained unrelieved during her stay in hospital, but her general condition improved conspicuously; she was mentally brighter, her appetite increased, and she gained weight.

Postoperative Metabolic Studies (see table)

Intravenous therapy with calcium gluconate was withheld for 10 days and, during the last 6 days of this period, mineral balances were determined. As in the preoperative studies, there was no net absorption of dietary calcium (see table, period C). The urinary output of both calcium and phosphorus was much less than in the preoperative periods, as was to be expected from their much lower serum levels (fig. 3). The overall metabolic picture now resembled that of uræmic osteomalacia (Stanbury and Lumb 1959).

Deprivation of calcium for a longer period was clinically unjustifiable, and metabolic studies were continued with a total daily intake of 2·19 g. of calcium (diet, 0·728 g.; oral calcium lactate, 1·148 g. Ca; intravenous calcium gluconate, 0·315 g. Ca). The addition of calcium lactate to the diet was not followed by significantly increased utilisation of calcium, and the net absorption (oral intake of calcium *minus* fæcal calcium) was no more than 0·12 g. Ca per day. During the 16-day period D, 0·41 g. of calcium was retained daily, but almost 80% of this was provided as intravenously injected calcium In all other metabolic periods the observed and theoretical (Reifenstein et al 1945) phosphorus balances were in close agreement, but in period D the calcium retention was not accompanied by an increased retention of phosphorus (see table) This suggests that the retained calcium may have been laid down in some form other than calcium phosphate During this metabolic period, the daily net intestinal absorption of phosphorus was 10 millimoles, and the serum-phosphate was low, on the other hand, the patient was absorbing 48 millimoles of sodium bicarbonate and the serum-bicarbonate level was normal There are reasonable grounds for thinking that the calcium may have been deposited mainly as carbonate (Sobel et al 1945)

The continued failure to utilise the calcium provided in the diet and as lactate was confirmed in metabolic period E (16 days), when the intravenous calcium gluconate was withdrawn The measured daily retention of 95 mg Ca with an intake of 1 88 g is at the limit of the error of the balance technique

In period F (12 days), therapy was augmented with 100,000 I U daily by mouth of vitamin D in the form of calciferol This failed to overcome the calcium malabsorption of the uræmic state, and the external balances and serum levels remained unchanged It was then necessary to terminate observations and allow the patient to return home

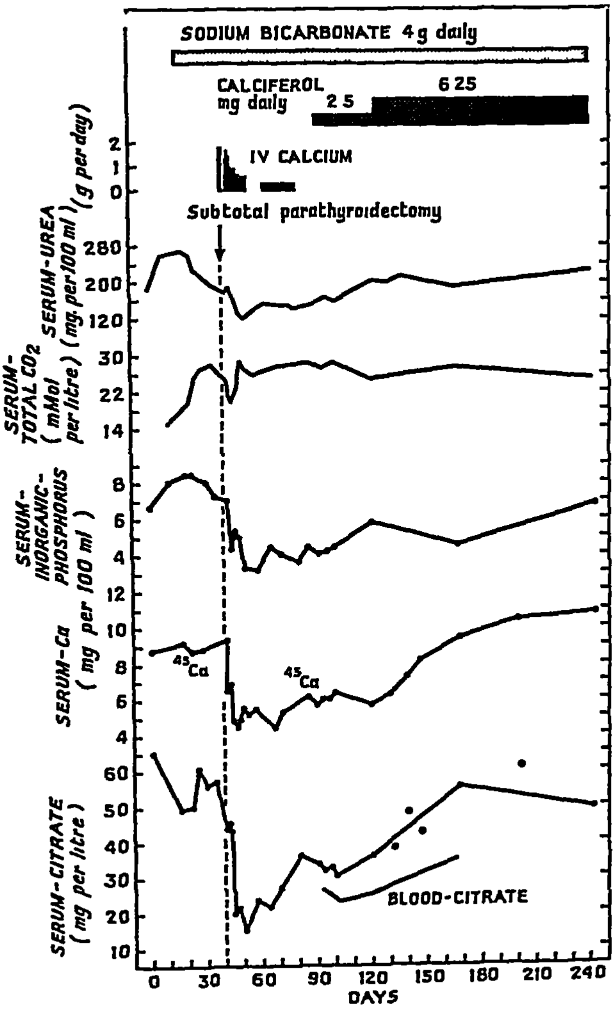

Fig 3—Biochemical changes in serum before and after operation.

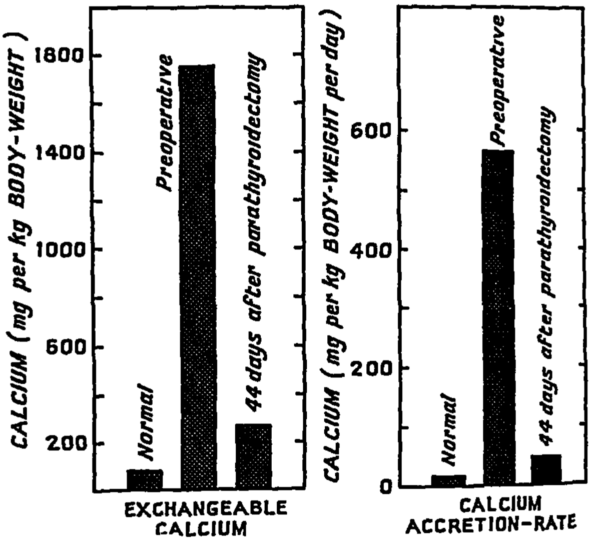

Fig 4—" Exchangeable calcium " and " calcium accretion rate before operation and 44 days after operation

Effects of Vitamin D

Although it seemed obvious from the metabolic measurements that 2 5 mg of calciferol was having no effect, the patient continued with this daily dose for a further 20 days as an outpatient Osseous pain and tetany continued, there was no detectable improvement in the radiographic appearances and no significant change in the serum biochemistry

On day 127, the daily dose of calciferol was increased to 6 25 mg Within days the patient began to feel better, and she commented particularly on the apparent increase in muscular strength The tetany and skeletal pain improved progressively thereafter and ultimately disappeared, the serum levels of calcium, phosphate, and citrate increased progressively, the radiographic appearances reverted dramatically towards normal (fig 2) 2 months later she was free of pain, could walk briskly, and was engaging in housework

Although we were unable to carry out metabolic measurements, we feel certain that the larger dose of vitamin D increased the net absorption and retention of calcium and phosphorus In our experience of treating uræmic osteomalacia we have sometimes found it necessary to increase the dose of calciferol to these levels when smaller doses (1 25–2 5 mg per day) have failed to overcome the " vitamin-D resistance " of the uræmic state (Stanbury and Lumb 1959) The very obvious radiographic evidence of remineralisation of the skeleton supports our belief that calcium and phosphorus had been effectively retained (figs 1 and 2)

Skeletal Exchanges with Radiocalcium

Studies of skeletal dynamics were made on days 24 and 84 (fig 3), using intravenously injected ^{45}Ca (7μC) The technique and the method of analysis of results were those of Bauer et al (1957) The derived data for " exchangeable calcium " and " calcium-accretion rate " are shown in fig 4, full details of these and other similar observations will be published elsewhere

Before operation the calcium-accretion rate, which provides an index of the rate of skeletal turnover, was 0 56 g per kg body-weight per day, or some sixty times the average normal (Heaney and Whedon 1958), the exchangeable calcium (1 76 g per kg body-weight) was correspondingly greatly increased

Parathyroidectomy produced a conspicuous fall towards normal in both these indices (fig 4) It is noteworthy that the postoperative value of 13 g (0 27 g per kg body-weight) for the readily exchangeable calcium was about three times the average normal. Moreover, between the first and second tests with radiocalcium, there had been a measured retention of approximately 20 g of calcium. Since the serum-calcium remained close to 5 5 mg per 100 ml, it is evident that neither the recently retained calcium nor the large depot of exchangeable calcium was *available* for maintenance of normal serum levels Presumably, there was lacking, in this phase of relative hypoparathyroidism, the active cellular mechanism (Neuman and Neuman 1958) which transfers calcium from bone to the circulating blood and which requires parathyroid hormone or vitamin D for its effective function.

Phosphate Excretion and Renal Clearance of Phosphate

Preoperatively the average daily net intestinal absorption of phosphorus was 0 48 g (≡45% of intake) and rather more than this was excreted daily in the urine. During the whole 50 days of postoperative metabolic study, the net daily absorption of phosphorus averaged 0 36 g (≡40% of intake), of which only some 50% (average, 180 mg per day) was excreted in the urine At first sight this reduced urinary output of phosphorus would be expected as a result of removing the phosphaturic influence of parathyroid hormone from the renal tubules, and the simultaneous fall of the 24-hour phosphate clearances (calculated as described by Stanbury [1958]) from 4 5 to 3 ml per min is equally reasonable. The reduction of urinary phosphorus and of phosphate clearance was, however, associated with an approximate halving of the serum-phosphate (fig 3), and this could account for the urinary changes without alteration of parathyroid function In fig 5 the serum-phosphate level is related to the simultaneously determined ratio of phosphate and creatinine clearances (C_P/C_{Cr}) It will be seen that the ratio C_P/C_{Cr} increased with the serum level of phosphate, as it does in the healthy individual with normal renal and parathyroid function (see Stanbury 1958) Goldman and Bassett (1954) showed that responsiveness to exogenous parathyroid hormone was lost in renal disease when the rate of glomerular filtration fell below 10 ml. per min. In the present patient the 24-hour creatinine clearance varied from 4 6 to 6 5 ml per min, and the C_s urea from 3 0 to 3 3 ml per min We consider that purely extrarenal factors, acting through change in serum-phosphate level, were responsible for the observed changes in urinary phosphorus The simultaneous fall in serum-calcium and phosphate after operation in our patient accords with the experimental observations of Talmage (1956) on parathyroidectomy in nephrectomised animals, and with the anomalous effects of exogenous parathyroid hormone in pseudohypoparathyroidism (Calcagno and Lowe 1956)—a condition in which the kidneys are supposed to be refractory to parathyroid hormone. At essentially similar levels of glomerular filtration and of intestinal absorption of phosphorus, the influence of the parathyroid on extrarenal tissues may thus be an important determinant of the serum-phosphate in patients with renal failure

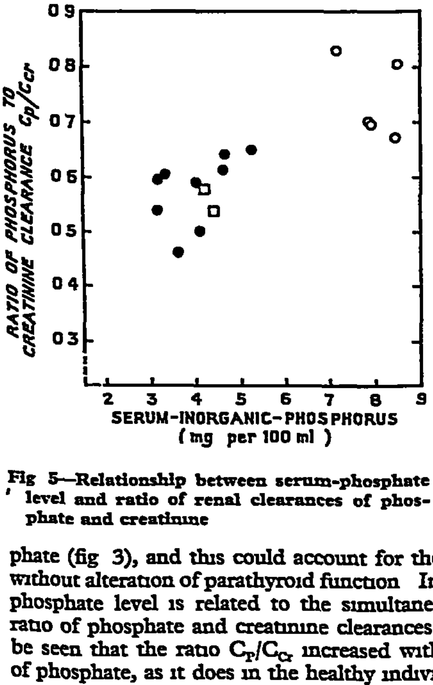

Fig 5—Relationship between serum-phosphate level and ratio of renal clearances of phosphate and creatinine

Citrate Metabolism

Before operation the serum levels of citrate were considerably increased (5–6 mg per 100 ml) rather than low as is usual in uræmia without bone disease (Nordmann et al 1959, Walser 1959, Lumb and Stanbury 1960) They fell rapidly to normal after parathyroidectomy, in parallel with the falling levels of calcium and phosphate The subsequent rise and the effects of therapy with vitamin D (see fig 3) are discussed in detail elsewhere (Lumb and Stanbury 1960)

Discussion

In adult patients with azotæmic osteodystrophy, Gilmour (1947) found a direct correlation between the degree of osteitis fibrosa and the weight of hyperplastic parathyroid tissue We have obtained similar findings in a smaller series of necropsy cases (Ball and Stanbury 1960) There are thus reasonable grounds for regarding parathyroid hyperfunction as responsible for renal osteitis fibrosa, even though many workers deny such a simple causal relationship (Snapper 1957, Bartter 1958) This contradictory view seems to originate in the authority of Albright (Albright et al 1937), who has stated his categorical belief that "the bone disease is not directly connected with the secondary hyperparathyroidism, but is entirely dependent on the associated acidosis which is invariably present" (Albright and Reifenstein 1948)

It has been noted (see table) that correction of the metabolic acidosis in the present case had no effect on the serum levels or external balances of calcium or phosphorus This has been confirmed in other studies We have, in fact, observed only two effects following the administration of alkalis in renal osteodystrophy one, the correction of a sodium deficiency, is beneficial, the other, the induction of the symptoms of tetany, is detrimental In our view, the present study establishes firmly a direct action of the enlarged parathyroid glands on the skeleton in this syndrome The immediate postoperative fall in the serum levels of calcium, phosphate, and citrate (fig 3), and the enormous reduction in the rate of skeletal turnover (fig 4), can be explained on no other basis Supporting evidence is provided by the less completely studied cases of Dreskin and Fox (1950) and Pollack and Siegal (1936)

We are satisfied that hyperparathyroidism developed in our patient as a result of chronic renal disease and that we were not dealing with a case of primary parathyroid hyperplasia and secondary renal disease Neither the gross nor the histological appearances of the resected glands corresponded to Castleman's (1952) description of primary hyperplasia On the contrary, they had appearances typical of Gilmour's (1947) type-IV hyperplasia, of which several examples complicating chronic renal disease have been described in recent years (e g, Richards 1951) The absence of nephrolithiasis or nephrocalcinosis, the history of polydipsia since childhood, and the presence of renal disease in a sibling, although individually inconclusive, suggest collectively that the patient had some congenital renal lesion The skeletal radiographs were typical of azotæmic osteodystrophy

It is a fact, none the less, that ablation of the parathyroid glands was not followed by spontaneous clinical healing of the skeletal lesions Although parathyroidectomy reduced the rate of skeletal turnover to a level close to normal, no significant retention of bone mineral occurred even when the dietary intake of calcium was greatly increased Clinical, and simultaneous radiographic, improvement took place only when the appropriate dose of vitamin D was given, and, from our many metabolic studies in uræmia, we are certain that these changes coincided with the bodily retention of calcium and phosphorus The immediate factor producing rickets or osteomalacia in uræmia appears to be some interference with, or antagonism to, the action of vitamin D (Liu and Chu 1943, Stanbury 1957, Stanbury and Lumb 1959), and this state of affairs is reflected in defective utilisation of dietary calcium and phosphorus with a tendency towards lowering of the serum-calcium level. It is our present belief that renal hyperparathyroidism is a secondary consequence of the intestinal malabsorption of calcium or the " apparent vitamin-D deficiency " of the uræmic state It is therefore of particular interest that the characteristic failure of calcium utilisation persisted in the present case when parathyroidectomy had produced overt *hypo*parathyroidism The metabolic abnormality primarily responsible for osseous disease thus appears to be uninfluenced by the state of parathyroid function Functional hyperparathyroidism is presumably a compensatory mechanism directed towards the production of a normal serum-calcium in the absence of one factor—the " vitamin-D effect "—that normally contributes to its maintenance If the parathyroid response is satisfactory, a normal serum-calcium may be achieved, but this may require a degree of parathyroid hyperfunction sufficient to engender parathyroid bone disease Restoration of the vitamin-D effect, by provision of a suitably large dose of the vitamin, would in this circumstance produce the hazard of hypercalcæmia Looked at in this way, the role of parathyroidectomy in the present case was to permit the subsequent safe administration of the large dose of vitamin D required to promote mineral retention (i e, to correct the fundamental metabolic defect) without causing metastatic calcification

It is necessary to attempt to resolve the apparent contradiction between the argument of the previous paragraph and our earlier comment reporting the reversal of secondary hyperparathyroidism by vitamin D It is, however, the secondary hyperparathyroidism *associated with azotæmic rickets or osteomalacia* that is demonstrably reversible in this way, as is also the secondary hyperparathyroidism in the osteomalacia of steatorrhœa (Nordin 1958) In all probability hyperparathyroidism always accompanies osteomalacia and certainly, in our osseous biopsy material from osteomalacia of different ætiological types (azotæmic, Fanconi syndrome, steatorrhœa, " primary vitamin-D resistance "), Ball (1959) almost invariably finds some degree of osteitis fibrosa This is always greatest in the azotæmic cases, and Gilmour (1947) found that children with the greatest parathyroid hyperplasia showed healing of the rachitic lesions and a residual extensive osteitis fibrosa Our interpretation of cases such as that described here is that the parathyroid glands, after a prolonged period of physiological stimulation, become autonomously hyperfunctional, what was originally a predominantly osteomalacic state becomes progressively transformed into parathyroid bone disease This hypothesis is extremely difficult to verify directly, but we have observed one patient whose osteodystrophy evolved in precisely this fashion and in whom the exhibition of large doses of vitamin D and the development of hypercalcæmia failed to produce involution of the parathyroid glands or disappearance of the osteitis fibrosa (see Stanbury 1957), figs H, J, K) Indirect support for the hypothesis is provided by the second case of Davies et al (1956)—a patient with cœliac disease and osteomalacia who developed evidence of parathyroid bone disease and actual hypercalcæmia It is irrelevant that in that patient apparent " adenomata " developed in two parathyroid glands, whereas in the present case the parathyroids had the histological appearance conventionally designated " hyperplasia " In the first place, the interpretation of parathyroid microscopic appearances is notoriously difficult and subjective, secondly, other endocrine glands—for example, the adrenal cortex (Stanbury and Mahler 1959)—appear sometimes to exhibit functional autonomy after prolonged stimulation without developing adenomata

It would clearly be reprehensible to undertake potentially hazardous surgery in a case of irreversible uræmia on the strength only of a hypothesis which is at variance with prevailing concepts We believe these concepts to be incorrect, and on the ethical score we are quite satisfied The patient, some 15 months after operation, and 7 months after discontinuance of therapy has a relatively normal (figs 1 and 2) and painless skeleton the serum-alkaline-phosphatase is normal (8 King-Armstrong units per 100 ml), the serum-calcium is 10 1 mg per 100 ml and the serum-phosphate 6 3 mg per 100 ml The serum-urea of 140 mg per 100 ml is less than it was when we first saw the patient, and her blood-pressure is normal Without this treatment she would certainly have remained a cripple in constant pain, we think she would have died of renal failure

Summary

A case is described in which gross skeletal changes of osteitis fibrosa complicated chronic azotæmic renal failure

Subtotal parathyroidectomy was performed in order to eliminate the hyperparathyroid bone disease, and remineralisation of the skeleton was effected by large doses of vitamin D The skeletal disease was clinically cured

Metabolic and radio-isotopic studies indicated that secondary hyperparathyroidism was probably responsible for the osteitis fibrosa and that the apparent " vitamin-D resistance " of the uræmic state was uninfluenced by the state of parathyroid function

We are greatly indebted to Mrs N Caris for technical assistance with the metabolic studies and to the various dietitians of the dietetic department of the hospital Dr E P Morley kindly referred the patient to us

Addendum

A second patient has been submitted to subtotal parathyroidectomy in an admittedly desperate attempt to relieve very severe azotæmic hyperparathyroidism

She was a woman of 35 years, who is known to have had progressive type-1 nephritis for 26 years Tragically, œdema of the glottis developed after intubation for anæsthesia, and tracheostomy was performed In relation to this there was a brisk secondary hæmorrhage, from which she died during the night of the 15th postoperative day The 4½ parathyroid glands removed (total weight 1 87 g) had the histological appearances of Gilmour's (1947) type-IV hyperplasia with formation of adenomatous nodules The functional effects of parathyroidectomy, assessed by changes in serum biochemistry, were the same as in the first patient The serum values were as follows before operation, urea 220 mg per 100 ml, calcium 9 8 mg per 100 ml, phosphate 7 0 mg per 100 ml, citrate 8 mg per 100 ml, on the 5th postoperative day urea 260 mg per 100 ml, calcium 6 1 mg per 100 ml, phosphate 5 2 mg per 100 ml, citrate 1 6 mg per 100 ml

INTIMAL AND MEDIAL LIPIDS IN HUMAN AORTAS

ELSPETH B SMITH
B.A. Cantab , Ph D Lond

From the Courtauld Institute of Biochemistry,
The Middlesex Hospital Medical School, London, W 1

THE origin of the lipids in atherosclerotic lesions is still unknown but clinical, experimental, and epidemiological experience continues to focus attention on a possible association with abnormal plasma lipids

The plasma lipids consist mainly of a mixture of triglycerides, cholesterol and its fatty-acid esters, and phospholipids, of which the main components are lecithin and sphingomyelin These circulate in the form of lipoproteins, which can be separated (by electrophoresis, ultracentrifugation or chemical fractionation) into two main divisions—the alpha or high-density lipoproteins and the beta or low-density lipoproteins It is the latter group which may be increased in clinical atherosclerosis Gofman and his coworkers (see for example, Gofman et al. 1954) have subdivided the low-density lipoproteins into groups according to their rate of flotation in the ultracentrifuge, the lower-density S_f20–400 fractions have a large particle size and high proportion of triglyceride, whereas the bulk of the cholesterol is carried in the higher density S_f0–12 fraction They concluded that the S_f20–400 lipoproteins had the strongest association with atherosclerosis but this is disputed

The lipid in each lipoprotein group has a characteristic composition, and the present investigation was undertaken with three objectives (1) to see whether careful analysis of intimal and medial lipids shows any identity with individual lipoprotein fractions, (2) to obtain information on the chemical changes occurring in intima and media with lesions of increasing severity, and (3) to see whether the data suggest a different origin for the lipid in different types of lesion

Materials and Methods

Analyses have been made on 56 tissue samples from 22 human aortas obtained at necropsy in the Bland-Sutton Institute of Pathology The cases consisted of 7 men aged 25–59, 5 men aged 60 and over, 4 women aged 52–59, and 6 women aged 60 and over They included myocardial infarcts (5), other heart conditions (5), cerebral hæmorrhage (2), carcinomas (5), diabetic gangrene, syphilitic atherosclerosis, pneumonia, and steatorrhœa

Where possible the whole length of the aorta from the arch to the bifurcation was obtained, homogeneous areas of normal or atherosclerotic intima were selected for analysis and ringed with a sharp scalpel, with the utmost care the intima was peeled off with curved forceps The adventitia and outer layers of the media were stripped from the corresponding area, and the inner layers of the media taken for analysis

Extraction —The wet tissue was weighed, then extracted with 25% ether in ethanol for four to seven days and 50% chloroform in methanol for twenty-four hours, both at room temperature in the dark, it was then ground to a powder and extracted hot with the latter solvent. The combined extracts were evaporated at 45–50°C. in a stream of nitrogen, the residue dried in vacuo and the lipids dissolved in 15% chloroform in petroleum ether

Separation of lipids —The lipids were separated into cholesterol esters, triglycerides plus free cholesterol (in most samples these groups were eluted together), and phospholipids on columns of 1 part celite to 2 parts silicic acid (Borgstrom 1952)

Total lipid and cholesterol —The total non-phospholipid fractions were weighed and their cholesterol content determined by the method of Bloor (1916)

Phospholipids —The phospholipid fraction was sampled for total phosphorus, then separated into lysolecithin, sphingomyelin, lecithin, and phosphatidyl ethanolamine by chromatography on silica impregnated papers (Lea et al 1955) The concentration of each component was measured by determining the phosphorus in the eluted spots

Lipid phosphorus was determined by a modification of the method of Allen (1940) giving a working range of 1–15 μg P

The chromatography was repeated if, between duplicates, the distribution differed by more than $2^1/_2$%, or the recovery from the chromatograms was less than 90% of the total phosphorus The average recovery of 43 duplicate estimations was 93%

Results

The average findings in the intima and media in normal areas and in lesions of different types are summarised in table I This shows the total lipid, cholesterol, and phospholipid concentrations in mg per 100 g wet tissue, the percentage of cholesterol and phospholipid in the total lipid, and the concentration and percentage of sphingomyelin and lecithin in the phospholipid fraction

Lysolecithin and phosphatidyl ethanolamine (P.E), although individually variable, have not shown any consistent trend, the average proportions are 5 5% in the intima and 3 5% in the media for lysolecithin, and 7 5% in the intima and 10 5% in the media for P E The lower lysolecithin and higher P E of media is a consistent finding, P E tends to disappear from necrotic lesions

Intimal and Medial Lipids in Normal Areas

Table I and fig 1 show that there are minor differences in the concentration of total lipid in normal intima and media and rather larger differences in composition, the intimal lipids contain about 40% cholesterol and 20%

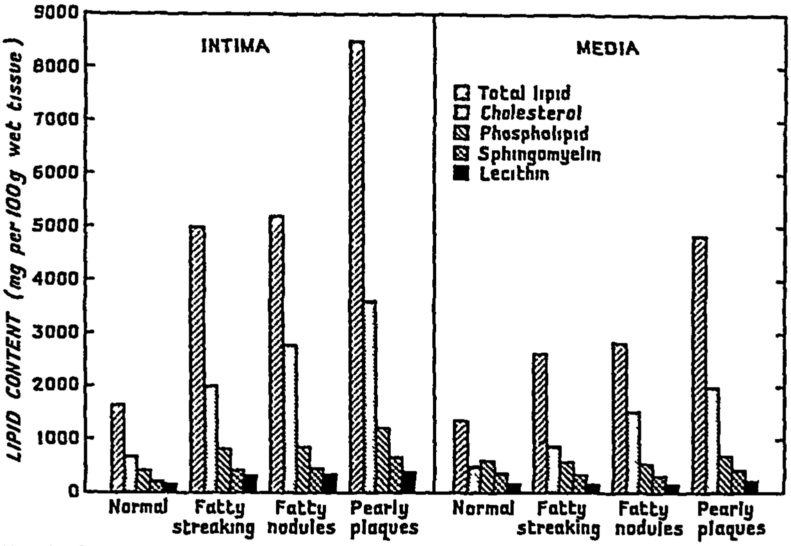

Fig 1—Average concentration of lipid components in normal and atherosclerotic areas of human aortas Intima and media are taken from the same sites

phospholipid with roughly equal parts of sphingomyelin and lecithin, whereas in the medial lipids there is less cholesterol and rather more phospholipid of which over 60% is sphingomyelin The free and esterified cholesterol also differ in the two regions, the proportion of free cholesterol in the media being almost double that in the intima This has been determined only on 6 cases, and the results are given in table II

It was expected that, in the one completely normal aorta (obtained from a case with steatorrhœa), and in aortas with mild atherosclerosis, normal areas of intima would contain less lipid than normal patches from severely diseased arteries Table III shows the results from 12 aortas, arranged in order of severity of atherosclerosis Most surprisingly, there is no obvious correlation between the lipid content of normal patches of intima (or the underlying media) and the severity or extent of atherosclerosis in the rest of the aorta

The lipid content of normal patches of intima shows a statistically significant correlation with the age of the subject, at ages over 35 For total lipid the correlation coefficient $r=0{\cdot}703$, $P<0{\cdot}02$, for cholesterol $r=0{\cdot}83$, $P<0{\cdot}01$ and the concentration increases by about 200 mg per decade There is no correlation between phospholipid content or composition and age, and the lipid content of the media shows no significant correlation although there is a small increase in cholesterol and fall in phospholipid at ages over 60 The highest intimal lipid concentration encountered in normal tissue was in an exceedingly obese woman with very mild atherosclerosis

Areas with Very Mild Atherosclerosis

In table IV normal intima is compared with areas of light fatty flecking and streaking in two young men, and light fibrous streaking from a woman aged 70 with myocardial infarction is compared with the average results for normal intima in cases over 60

In both young men the cholesterol is low in the normal intima, and in the fatty lesions it increases more than the other lipids In the first case the cholesterol is more than trebled, while total lipid and phospholipid increase about $1\frac{1}{2}$ times, in the second case the change in cholesterol is much greater, occurring mainly in the ester fraction which increases 12 times

TABLE II—PROPORTION OF CHOLESTEROL IN THE UNESTERIFIED FORM IN NORMAL AREAS OF INTIMA AND MEDIA

Age	% of total cholesterol unesterified	
	Intima	Media
25	59·0	74·5
52	35·5	53·7
53	38·9	60·8
55	27·6	68·1
60	29·6	48·5
60	24·2	57·7
Average	35·8	60·5

In the fibrous streaking the lipid differs little from that in normal intima in the same age-group

In both the young men there is a small but definite increase in the lipids of the media, suggesting that it is to some extent involved in even these most superficial lesions

TABLE I—LIPIDS IN NORMAL AND ATHEROSCLEROTIC INTIMA AND MEDIA

Tissue analysed		Lipid content of wet tissue (mg per 100 g)					% of total lipid		% of total phospholipid	
		Total lipid	Cholesterol	Phospholipid	Sphingomyelin	Lecithin	Cholesterol	Phospholipid	Sphingomyelin	Lecithin

Changes with Increasing Atherosclerosis

The progressive changes in more established lesions are most easily followed in the block diagram in fig 1, which shows the concentration of different lipids in mg per 100 g wet tissue In areas of fatty streaking there is a threefold increase in the intimal lipid and a doubling of the medial lipid giving nearly twice the concentration in the intima as in the media—a relationship which is approximately maintained in more advanced lesions Total lipid and cholesterol increase steadily in both intima and media, but the total phospholipid rises only slowly in the intima and remains almost constant in the media In the intima lecithin remains rather constant, but the concentration of sphingomyelin rises steadily and largely accounts for the increase in total phospholipid, whereas in the media there is little change in either component The trends shown by these pooled results are also shown by lesions of different severity taken from the same aorta

Advanced and Necrotic Lesions

In advanced lesions the concentration of lipid falls, this is illustrated in table I and for 1 case in fig 2, which shows the concentration of different lipids in pearly plaques, calcified pearly plaques, and calcified "pipes" The fall in lipid concentration could result from dilution with calcium salts or from breakdown or leaching-out of some lipid components, the latter is probably the main factor since there is little change in the concentration of residual lipid (total lipid-[cholesterol+phospholipid]), while sphingomyelin, which is the most stable and insoluble component, accounts for most of the remaining phospholipid The last group in table I shows the results obtained on scraped-out atheromatous "porridge" In the younger cases this was a bright yellow pool lying between intact pearly plaques and apparently intact elastic tissue (although its lipid content was high), nearly 20% of the wet material was lipid, of which over half was cholesterol, but the lipid pattern does not appear to be fundamentally different from that found in superficial lesions In the older case the "porridge" was pressed out from the craters of ulcerated plaques and had a brownish colour, the phospholipid was very low, and 70% of it was sphingomyelin

Discussion

Several factors must be considered

1 Because there is a progressive chemical change in lesions at different stages of development, any hypothesis on the origin of the lipids should be based on the composition of early and intact lesions, rather than complicated and necrotic ones

2 There are differences between intimal and medial lipids These tissues should, as far as possible, be studied separately otherwise the analyses will have little meaning and important

TABLE IV—LIPIDS IN MILD ATHEROSCLEROSIS

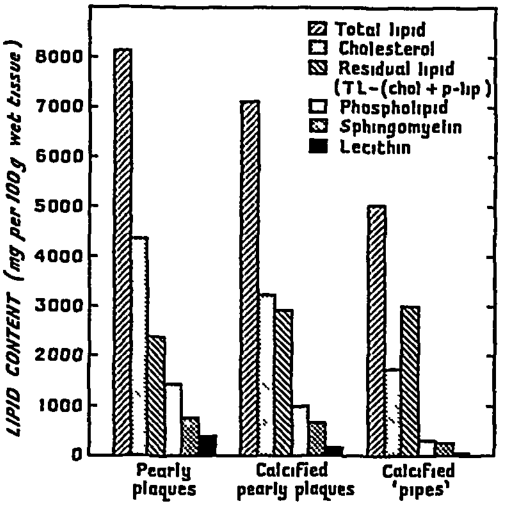

Fig 2—Changes in the concentration of different components in increasingly necrotic lesions from the aorta of a former case of syphilis with gross atherosclerosis

changes may be obscured The discrepancies in the results published from different laboratories may largely arise from analysis of tissue samples containing mixtures of intima and media and of lesions in different stages of development

3 The lipid content is characteristic for the local condition of the intima rather than for the vessel as a whole, and in areas of normal intima it is not correlated with the severity of atherosclerosis

4 The total lipid and cholesterol content of normal areas of intima increase with age

Comparison of Plasma and Aortic Lipids

From published data and results obtained in this laboratory an assessment of the average composition of the lipids in plasma and aorta has been attempted, and they are compared in table v The lipids of whole plasma and of intima differ mainly in their phospholipid components Those of the isolated S_f20–400 lipoproteins and intima differ in all respects The S_f0–12 lipoproteins resemble the lipids in normal intima from older cases reasonably closely, and it is of interest that Paterson and coworkers (1956) found that in serum analysed before death this was the only class of lipoprotein which showed a positive correlation with the degree of atherosclerosis at necropsy This is the main lipid-bearing component in most plasmas, so, if intimal lipids are derived from plasma, it would not be surprising if it had a greater influence than other lipoprotein fractions Its possible influence on atherogenesis is difficult to judge, because of the patchy nature of the lesions, and because of the observation that in severe atherosclerosis there is no increase in the lipid content of normal areas of intima while in the earliest lesions there is a disproportionate increase in cholesterol

TABLE V—LIPID DISTRIBUTIONS IN PLASMA FRACTIONS AND AORTIC TISSUE

—	% of total lipid		% of cholesterol unesterified	% of sphingomyelin in the phospholipid
	Cholesterol	Phospholipid		
Whole plasma	30–35	30–35	25–30	18
S_f 20–400 lipoproteins *	14	20	48	20
S_f 0–12 lipoproteins	40	27	25	40
High density (α) lipoprotein *	20	45	33	15
Normal intima, under 40 years	25	38	59 (1 case)	30–45
Normal intima over 40 years	35–45	20–30	25–35	45–50
Normal media all ages	25–30	35–55	55–75	45–65
Early intimal lesions	45–58	15–20	35–45	50 & upwards

* Includes data from Landgren et al (1955)

The composition of the fatty acids in aortic and plasma cholesterol esters has recently been determined in several laboratories, and Wright, Pitt, and Morton (1959) compare and discuss the data The discrepancies between the results of different laboratories are so great that the problem has not, so far, been clarified by this work

Synthesis of Lipid in Arterial Wall

Zilversmit (1959) has clearly demonstrated the incorporation of ^{32}P into arterial phospholipids, and he estimates that in the cholesterol-fed rabbit nearly 90% of aortic phospholipid is synthesised in situ He finds the specific activities in the intima and media+adventitia to be about the same, which is compatible with the observation in man that the lipid increases in both layers in a uniform manner, although in this case at a faster rate in the intima Even in the most superficial fatty streaking the medial lipid shows some increase, suggesting that the media is involved at all stages of atherogenesis

Experimental information on cholesterol synthesis is less conclusive, but in early fatty streaks it is difficult to reconcile the disproportionately large increase in cholesterol esters, relative to other lipids, with an uptake of plasma lipids, if phospholipid was rapidly eliminated one would expect a considerable increase in the proportion of sphingomyelin, but this does not occur In both blood and arterial tissue ^{32}P is incorporated into sphingomyelin slowly, suggesting a low metabolic activity thus the increasing proportions of sphingomyelin in the phospholipid of older lesions is more likely to result from its slow rate of catabolism than from a rapid rate of synthesis or deposition A low proportion of phospholipid which has a high sphingomyelin content may prove to be a useful indicator of old lipid deposits

It was hoped that careful studies on its composition might indicate whether the lipid in different types of lesion had the same origin it seemed reasonable to postulate that the lipid in the fatty streak might come from plasma whereas that under a pearly plaque might come from the arterial wall The steadily progressive changes in both composition and concentration of lipid in lesions of increasing severity, the similarity of composition of the lipids in yellow flecks and fibrous streaks, and the unremarkable composition of the lipid pool all seem to refute this idea, and to support instead the view that the fatty fleck and the mature plaque are part of a continuous process

Summary

Intimal and medial lipids have been analysed in normal and atherosclerotic areas from 22 human aortas, with particular attention to the distribution of individual phospholipid components

In normal areas the concentration of lipid in intima and media is similar, but its composition differs in the proportions of free and esterified cholesterol, in the proportions of cholesterol and phospholipid, and in the proportions of the lecithin and sphingomyelin components of the phospholipid

The lipid content appears to depend mainly on the local condition of the intima There is no correlation between the severity of atherosclerosis and the lipid content of normal patches of intima or media There is, however, a significant correlation between age and the normal intimal concentration of total lipid ($P < 0.02$) and of cholesterol ($P < 0.01$)

In lesions of increasing severity both intimal and medial lipids increase in a uniform manner, and there is some increase in the lipid of the media underlying even the earliest fatty flecking In more advanced lesions there is an increase in the proportion of sphingomyelin in the intimal phospholipid, and in necrotic lesions it may account for 70–80% of the phospholipid

The composition of aortic lipids is compared with that of whole plasma and of isolated plasma lipoprotein fractions A close resemblance is found between the lipids in the S_f0–12 lipoproteins and in normal intima

I wish to thank the Medical Research Council for their financial support, Sir Charles Dodds for his helpful encouragement and the provision of excellent facilities, Miss P A Wilkinson for help with cholesterol determinations, and the staff of the Bland-Sutton Institute of Pathology for their kind help in providing postmortem material

EFFECT OF CARBUTAMIDE ON HEPATIC GLYCOGENOLYSIS ACTIVATED BY GLUCAGON

A STUDY USING HEPATIC-VEIN CATHETERISATION IN NON-DIABETIC SUBJECTS

EKREM SERIF EGELI
M D
PROFESSOR AND DIRECTOR

HALÛK ALP

3RD CLINIC OF INTERNAL MEDICINE,
UNIVERSITY OF ISTANBUL, TURKEY

MANY opinions have been expressed about the mechanism of action of the antidiabetic sulphonamides, but investigations suggest that the main sites of action are the liver and the pancreas Evidence has been obtained that the sulphonylurea compounds increase the secretion of insulin by affecting the β-cells of the pancreatic islets (Colwell et al 1956, Loubatière 1956) In-vitro experiments on the effects of the sulphonylureas on the liver bring to mind the inhibition of glycogenolysis (Berthet et al 1956, Kaldor and Pogatsa 1959) In this study we investigated the effect of carbutamide upon hepatic glycogenolysis activated by glucagon in non-diabetics

The Investigation

We studied ten non-diabetic males with no clinical or biochemical evidence of liver disease They had a daily diet of carbohydrate 200 g, protein 80 g, and fat 70 g for a week. Next day, when hepatic catheterisation was to be performed they had no breakfast The catheter was inserted into the right lobe of the liver, and was left in place throughout the experiment Blood samples were drawn from the liver and fingertip simultaneously at 10-minute intervals, and their glucose levels were determined Inorganic phosphorus was also determined in the blood from the hepatic vein

In two cases glucagon 1 mg was injected intravenously, and changes in the glucose levels of the blood specimens from the hepatic vein and fingertip were measured for 90 minutes

Carbutamide 3 g was then given intravenously to three pairs of patients 10, 20, and 30 minutes respectively after the injection of glucagon 1 mg intravenously Two other patients were given glucagon 1 mg and carbutamide 3 g intravenously at the same time (Carbutamide was injected during the first 2 minutes and glucagon was given immediately afterwards)

Glucose was estimated by the Hagedorn-Jensen method, and inorganic phosphorus by the Subbarow-Fiske method

Results

At the beginning of the experiment the average hepatic-vein blood-glucose of the ten subjects was 115 4 mg per 100 ml, and their capillary blood-glucose was 103 2 mg per 100 ml Thus the average difference between the hepatic-vein and capillary blood glucose (H V -capillary difference) was 12 2 mg The individual results are shown in the table

In two subjects (cases 1 and 2), who had glucagon only, the H V -capillary blood-glucose difference rose by 50–65 mg and did not fall to the original level within 75 minutes

In cases 3 and 4, 30 minutes after the injection of glucagon, the H V -capillary blood-glucose differences were 35 and 47 mg per 100 ml But 10 minutes after carbutamide 3 g was given intravenously the H V -capillary difference dropped to 10 and 5 mg per 100 ml

In two other subjects (cases 5 and 6) carbutamide was injected 20 minutes after glucagon. The H V -capillary blood-glucose differences, which were 132 and 55 mg per 100 ml during the injection of carbutamide became 46 and 9 mg per 100 ml 10 minutes afterwards

Cases 7 and 8 were given carbutamide 10 minutes after glucagon. Their H V -capillary blood-glucose differences, which were 84 and 112 mg per 100 ml during the injection of carbutamide, dropped to 22 and 65 mg per 100 ml 10 minutes later

Thus in all six cases which had carbutamide at various intervals after glucagon the H V -capillary blood-glucose differences had dropped below the initial levels by the end of the experiment

In cases 9 and 10 glucagon was given intravenously within 30 seconds of the injection of carbutamide The H V -capillary blood-glucose differences rose to 20 and 25 mg per 100 ml, but they had dropped below the initial levels at the end of the experiment 10 minutes after the injection of carbutamide the average decrease of glucose was 10 5 mg per 100 ml in the capillary blood and 42 1 mg in the hepatic-vein blood

Discussion

Glucagon is regarded as an effective glycogenolytic agent, and our findings confirm this view In the ten subjects who had fasted for 14 hours the average hepatic-vein blood-glucose was 115 4 mg per 100 ml, and it rose to 211 5 mg per 100 ml 10 minutes after the injection of glucagon The average capillary blood-glucose was 103 2 mg per 100 ml after fasting, and it rose to 134 mg per 100 ml 10 minutes after the injection of glucagon This shows that hepatic glycogenolysis is activated by glucagon

We observed that the blood-glucose, which was elevated by glucagon, was definitely lowered within 10 minutes of the intravenous injection of carbutamide after various intervals, the average fall in hepatic-vein blood-glucose was 42 1 mg per 100 ml, while that in the capillary blood was 10 5 mg per 100 ml These findings signify that glycogenolysis activated by glucagon is blocked by carbutamide, but how this inhibition takes place has yet to be clarified Various enzymes are known to be concerned in glycogenolysis, taking part in several stages from the glycogen molecule being broken up until free glucose passes into the blood After glycogen is converted to glusoe-1-phosphate by the phosphorylase enzyme, and after this is converted to glucose-6-phosphate, the inorganic phosphate is broken up by glucose-6-phosphatase to form free glucose. Glucagon has been

claimed as a phosphorylase activator (Sutherland and Wosilait 1956, Rall et al 1957) Carbutamide probably blocks one or more of the enzymes taking part in glycogenolysis Some investigators have found that sulphonylurea compounds act on glucose-6-phosphatase and others think they do not (Ashmore et al 1956) In another study not yet published we have estimated glucose-6-phosphatase activity of the liver from material obtained by puncture biopsy before and after treatment with sulphonylurea compounds, and in diabetics we found moderate inhibition of enzyme activity after treatment Thus the inhibition of glucose-6-phosphatase may also be responsible for the blocking of the glycogenolytic effect of glucagon by carbutamide

There is strong evidence that the sulphonylurea compounds increase the secretion of insulin from the pancreatic β-cells But we still do not know how much the secretion of insulin is responsible for the blocking effect of carbutamide upon glycogenolytic activity of the liver activated by glucagon

Because the changes in inorganic phosphorus of the hepatic-vein blood after injections of glucagon and carbutamide were not consistent we shall not discuss them.

Summary

The effect of carbutamide 3 g intravenously on hepatic glycogenolysis activated by glucagon was investigated in ten non-diabetic subjects by means of hepatic-vein catheterisation

The glycogenolytic action of glucagon was blocked by carbutamide, and this effect is probably related to the inhibition of hepatic enzymes

The glucagon was kindly supplied by Eli Lilly & Co , Indianapolis, Indiana, U S A , and the injectable carbutamide by C H Boehringer Sohn, Mannheim, Germany

BULLET WOUND OF HEART AND RIGHT LUNG WITH RECOVERY

M Efthymiadis
Med Dip Athens
LATE REGISTRAR IN THORACIC SURGERY,
VICTORIA HOSPITAL, BLACKPOOL

Penetrating wounds of the heart and great vessels have attracted attention since the days of Harvey Indeed, the earliest attempts at surgical intervention in cardiac disorders were derived from experience gained in the repair of stab wounds of the myocardium Improved transport in World War II together with modern techniques of resuscitation, anæsthesia, and surgery considerably improved the results in the treatment of missile wounds of the heart and great vessels and are still associated with a high mortality, but under favourable conditions much can be done to save life (see Nicholson 1945, Harken 1946, Samson 1948, Maynard et al 1956, d'Abreu 1958)

Bullet wounds of the heart are unusual in civilian practice In the case described here a youth was accidentally shot through the heart and the right lung

Case-record

An 18-year-old youth was brought into the casualty department on Aug 5, 1959, with a history of being accidentally shot at a fun-fair from very close distance He had walked about 100 yards and then collapsed

Examination

The patient was critically ill He was pale, restless, and drowsy, with cold profuse sweats, no palpable pulse and an unrecordably low blood-pressure A small 3×3 mm entry wound was seen at the right second intercostal space just lateral to sternal margin, there was no exit wound The breath sounds were normal on the left side, but grossly diminished on the right, with tympanitic resonance anteriorly and dullness all along the posterior aspect The heart sounds were weak, but otherwise normal, no murmurs, no rub The veins in the neck were not engorged On abdominal examination there was some tenderness and guarding in the right hypochondrium

Right-sided exsanguinating hæmopneumothorax was provisionally diagnosed, and immediately a double intravenous drip was established (one in each arm) and plasma and dextran were given quickly Blood was taken for urgent cross-matching, and the chest and abdomen were radiographed, after which the patient was transferred to the operating-theatre for urgent thoracotomy

The chest X-ray showed almost complete opacity of the right chest with some pneumothorax on the lateral view, mediastinal displacement to the left, and a bullet in four fragments at the level of 8th to 9th rib posteriorly, also some spill-over in the left lung field from hæmorrhage into the bronchial lumen

Operation

A full posterolateral right thoracotomy was carried out through the bed of the 6th unresected rib There was massive hæmothorax, and about 4 pints of blood and clots were sucked out Following this hæmopericardium was noticed immediately, with two puncture holes through which blood was pouring The pericardium was widely opened, and a fair amount of blood and clots were sucked out, there was a $^{3}/_{4}$ in tear of the right auricular appendage near the opening of the superior vena cava In addition there was laceration of the middle and lower lobe, with rather heavy bleeding from pulmonary vessels, particularly in the interlobar fissure The bullet had passed $^{1}/_{2}$ cm laterally to the internal mammary vessels without damaging them, through the pericardium, right auricular appendage, pericardium again, middle lobe, interlobar fissure, and lower lobe, and had lodged in the lateral chest wall above the diaphragm near the vertebral column at the level of 8th to 9th ribs The laceration in the auricular appendage was clamped and repaired with no 60 thread mattress sutures The pericardium was then closed with interrupted sutures, leaving large gaps between them The holes in the lung were closed with fine thread sutures, and the bleeding was controlled similarly Finally the four fragments of the bullet were removed from the chest wall On inflating the lung there was no appreciable leak, and the lung appeared to have good aeration, except part of the lower lobe which had filled with blood The chest was closed with two drains (apical and basal) During the operation and immediate postoperative period 9 pints of blood was given Chest X-ray on the table at the conclusion of the operation showed a satisfactory appearance

Progress

The immediate postoperative course was satisfactory On the third day suction was applied through a bronchoscope, as the left main bronchus had been blocked by a plug of mucus and clot By the fourth day the leak had stopped and the drainage tubes had been taken out There was no fibrillation or any other cardiac irregularity, and the patient was discharged home, two weeks after the injury, on Aug 19

Four weeks later he was seen in the outpatient clinic, and thorough examination revealed no abnormality Chest X-ray showed slight elevation of the right diaphragm, but otherwise normal appearances

Discussion

In this case, despite the severity of the injury, with a $^{3}/_{4}$ in tear in the wall of the right atrium and perforations in the pulmonary vessels, the patient was able to walk 100 yards or so in search of help before he collapsed This is unusual, but not unique Undoubtedly, the speed with which the patient was transferred to hospital a mile or so away contributed to the successful outcome, and the proximity of transfusion apparatus and the immediate institution of a plasma infusion in each arm before moving the patient to the operating-theatre prevented further deterioration during critical moments

It has been suggested (DeBakey et al 1955) that puncture wounds of the heart tend to seal off so that the tamponade effect of the blood contained in the pericardium can be overcome by simple needle aspiration The advocates of this procedure suggest that the mortality resulting from it is much less than that from open surgery In the experience of others, however (Maynard et al 1956), aspiration alone cannot be relied upon either to relieve the tamponade or to remove blood, which may have already clotted

In the present case, immediate thoracotomy disclosed in addition considerable hæmorrhage from large pulmonary vessels, which itself would almost certainly have proved fatal if the patient had been treated conservatively Postoperatively, suction drainage maintained the lung in full contact with the chest wall throughout the pleural cavity, ensuring sealing of air leaks and preventing collection of effusion within the pleura

This case also illustrates the importance of keeping a close auscultatory watch on the opposite lung, whose aeration became embarrassed, owing to a plug of mucus in the opposite main bronchus, several hours before this was at all apparent radiologically

It is a remarkable tribute to the resilience of youth and to the excellent nursing care which he received that this young man was ambulant and well enough to return home from his " holiday " in Blackpool fourteen days after his injury

I am indebted to Mr P Jewsbury, consultant thoracic surgeon, Blackpool Victoria Hospital, for help and for permission to publish

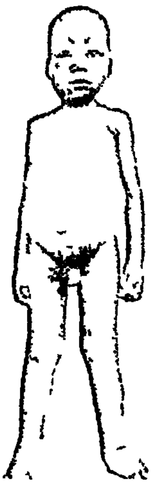
Preliminary Communication

POSSIBLE ÆTIOLOGICAL ROLE OF *PLASMODIUM MALARIÆ* IN "NEPHROTIC SYNDROME" IN NIGERIAN CHILDREN

A HIGH incidence of the "nephrotic syndrome" has been observed in children attending University College Hospital, Ibadan Between March, 1959, and January, 1960, 48 new cases were seen at the "nephrotic clinic" in the children's department By way of comparison, fewer than 12 cases were observed over an eighteen-month period among all children attending the three largest general hospitals in Durban, South Africa,[1] [2] one of which has a turnover of African children thrice that of University College Hospital, Ibadan Because of the very high incidence of the nephrotic syndrome in Ibadan, these cases have formed the basis of a special study This communication is a preliminary report of some of our findings



Clinical Features

On first attendance all our patients exhibited gross œdema, massive albuminuria, and severe hypoproteinæmia, no azotæmia, and a normal blood-pressure The clinical appearance of a typical case is shown in the accompanying figure

Biochemical Findings

The salient biochemical findings are given in table I together with values for normal Nigerian children in the same age-group These examinations were performed utilising standard techniques in the department of chemical pathology, University College Hospital The serum-cholesterol concentrations were variable, but the majority of children had values above those found in "normal" Nigerian children It should be noted that the blood-urea concentrations were within the "normal" range

TABLE I—MEAN BIOCHEMICAL VALUES IN NEPHROTIC AND "NORMAL" CHILDREN

—	Total serum-protein (g per 100 ml)	Serum-albumin (g per 100 ml)	Serum-globulin (g per 100 ml) α_1	α_2	β	γ	Serum-cholesterol (mg per 100 ml)	Blood urea (mg per 100 ml)
Nephrotic children								
Mean	4 38	0 62	0 37	0 96	0 73	1 70	265	18·0
Range	6 90–3 00	2 04–0 06	0 62–0 14	1 57–0 41	1 13–0 36	3 07–0 76	560–47	23–9
*'Normal' Nigerian children**								
Mean	6 90	3 20	0 30	0 80	0 90	1 70	101	13
Range							58–198	2–26

* J Edozien, personal communication

Percutaneous Renal Biopsy

This procedure has so far been carried out on 18 patients Prof G M Edington has made a preliminary summary of his histopathological findings to date, as follows

> "In general it can be said that the renal biopsies showed uniform histopathological changes There were patchy lesions of varying severity in the glomeruli with associated tubular degenerative changes Round cell infiltration of the interstitial tissue of varying severity was an inconstant finding The overall picture is similar to that described in an Ellis type II nephritis"

Ætiological Role of P malariæ

In view of the work of Giglioli,[3] who demonstrated a relationship between *P malariæ* and the "nephrotic syndrome" in British Guiana, it was decided to investigate the possible ætiological role of *P malariæ* in Nigerian "nephrotic" children

Three groups of children aged 3–10 years were selected. One of the groups consisted of children with the "nephrotic syndrome" The second group consisted of children with various illnesses other than nephrosis The third group were "healthy" children living in their own environment in a village close to Ibadan

Thick and thin blood-films were taken from all these children and were examined for the presence of plasmodia before any treatment for malaria was given The incidence of *P malariæ* in the three groups of children is shown in table II

It will be noted that the overall incidence of *P malariæ* infection in the nephrotic children is very much higher than that found either in the ill but non-nephrotic children or in the group of "healthy" village children

TABLE II—INCIDENCE OF *P malariæ* IN NEPHROTIC AND NON-NEPHROTIC CHILDREN (AGED 3–10 YEARS)

Group	No examined	*P falciparum* + *P malariæ*	*P malariæ* only	Overall *P malariæ* infection rate	*P falciparum* only	No parasites seen
Nephrotic children	48	45 8%	43 8%	89 6%	2 1%	8 3%
Non-nephrotic ill children	800	18 0%	6 0%	24·0%	52·0%	23·0%
'Healthy' children	200	12 0%	11 0%	23 0%	41 0%	33·0%

Treatment

Standard symptomatic treatment was given to all the nephrotic children They were divided by random sampling into two groups, group A received antimalarial therapy, whilst group B did not At the time of writing no differences in the course of the illness have become apparent in the two groups

Comment

Our findings indicate a definite relationship between the nephrotic syndrome in Nigerian children and infection with *P malariæ* The exact nature of this association has still to be elucidated Eradication of malaria in

New Inventions

AN EASY METHOD FOR THE DETERMINATION OF THE pCO_2 OF THE BLOOD

A PORTABLE syringe electrode system for measuring the pH of the blood was reported in this journal in 1957 [5] This apparatus has now been modified so that the pCO_2 of blood can be measured according to the technique described first by Kahn [6] and then by Astrup [7]

The pH of a sample of blood is measured at 37°C, and the value found is known as pH (1) The blood is then centrifuged and a gas mixture containing 5% CO_2, saturated with water vapour and at 37°C, is bubbled through the plasma If the pCO_2 of the plasma is different from that of the gas mixture, CO_2 will be lost or gained until the two levels of CO_2 are the same This change in the pCO_2 of the plasma will result in a change in the plasma pH, and the new value, pH (2), will bear a fixed relation to the original pH (1), the pCO_2 of the gas mixture, and the original pCO_2 of the blood This latter value can be read off the nomograms found in the papers of both these authors

This method is as accurate as any other method in current use for the determination of pCO_2 Its advantage lies in the ease with which the measurements are made. The accuracy of the method depends on the apparatus used and very little technical skill or training is required A large gas cylinder will last for many months in daily use, and it need be analysed only once

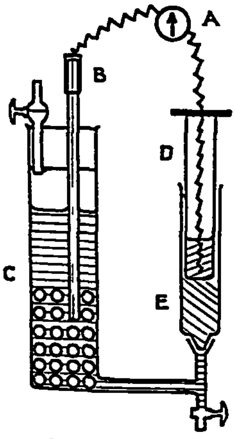

Fig 1—Scheme of apparatus

A=pH-meter
B=calomel electrode
C=supersaturated potassium-chloride solution.
D=glass electrode.
E=barrel of syringe.

Apparatus

The pH measuring apparatus previously described consists of a glass electrode which forms the tip of the plunger of a syringe Blood is taken into this syringe, and the syringe is connected directly to a calomel electrode The whole apparatus is immersed in a water-bath at 37°C

In order to make the pCO_2 measurements the following modifications are made (fig 2)

3 ft. of nickel tubing is wound round a 'Perspex' tube which passes through, and is supported by, the lid of the water-bath The perspex tube contains saline, and, after passage through the nickel tube and the saline, the warm saturated gas is collected from the airspace at the top of the perspex tube and is delivered through a 2 mm.-bore needle to the bottom of the syringe barrel, which also passes through, and is supported by, the water-bath lid

A perspex obturator with a small hole up the middle fits into the syringe barrel

Technique for Determination of pCO_2 of Blood

1 5 ml of blood is taken anaerobically into an oiled syringe containing oxalate-fluoride mixture which prevents clotting and inhibits metabolism

2 Approximately 1 ml of this is transferred anaerobically to the syringe electrode and pH (1) is measured

3 The rest of the blood is centrifuged for five minutes and the supernatant plasma is sucked off During this time gas is bubbled through the humidifier in order to saturate the saline with CO_2

4 The syringe electrode is washed out and connected to the needle which delivers the gas mixture, and the whole is immersed in the water-bath The obturator is put in the syringe and the hole in its centre is filled with plasma The plasma is allowed to warm up for five minutes, until it reaches water-bath temperature, at which it must be kept throughout the rest of the procedure

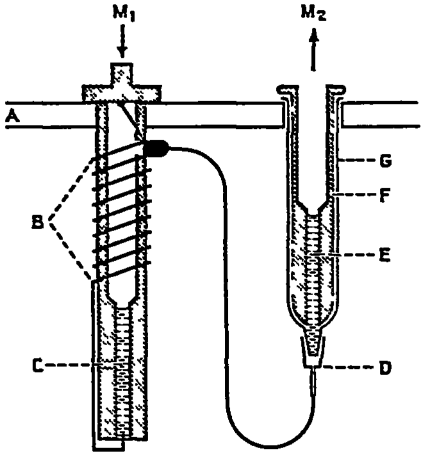

Fig 2—(A) water-bath lid, (B) heating coils, (C) saline in humidifier, (D) gas delivery needle, (E) plasma, (F) 'Perspex' obturator, (G) syringe barrel, (M_1, M_2) gas mixture, the arrows indicate the direction of the flow

5 After temperature equilibrium is reached, the gas mixture is bubbled through the plasma at a rate of 40 ml per minute, for ten minutes Some samples of plasma form froth more easily than others and the froth may rise above the level of the water in the water-bath and cool down It is very important that the temperature should be maintained throughout the equilibration and, when necessary, frothing is prevented by the addition of a drop of caprylic alcohol

6 The obturator is then removed, and the space above it fills with the gas mixture after some seconds The gas supply is cut off, the glass electrode plunger is quickly inserted into the barrel, and the gas delivery needle is disconnected The gas in the syringe is expelled and the pH of this gas-equilibrated plasma, pH (2), is then measured

7 The pCO_2 of the gas mixture is accurately measured when the cylinder is new, and thus the pCO_2 of the plasma after equilibration is accurately known From the two pH readings and the equilibrated pCO_2 value, the original pCO_2 of the blood can be read off a nomogram

Greater precision in the measurement of pCO_2 can be achieved if the sample of plasma is equilibrated a second time with gas of a different pCO_2 For all ordinary clinical purposes, however, a single equilibration is all that is necessary, giving as it does a result within ±2 mm of those obtained by other methods

The apparatus can be obtained from Electronic Instruments Ltd., Lower Mortlake Road, Richmond, Surrey

Reviews of Books

Clinical Toxicology

C J POLSON, M D, F R C P, barrister-at-law, professor of forensic medicine, University of Leeds, R N TATTERSALL, M.D, F R C P, assistant physician, Leeds General Infirmary London English Universities Press 1960 Pp 589 42*s*

FROM the vast range of poisons and poisoning the authors have gathered information and entertainment about poisoning in the home, and they present this impressive amount of knowledge in a way particularly designed to help the clinician who may have to treat, with scant warning, a poisoned patient The first part of the book deals briefly but clearly with the British law relating to poisons and poisoning and with the general principles of the diagnosis and treatment of poisoning The doctor is advised about how to conduct his investigations when there are grounds for suspicion, and the little-known point is made that removal of a victim to hospital does not necessarily end the danger of continued criminal poisoning

The second and larger part of the book is devoted to accounts of the diagnosis and treatment of poisoning by specific poisons, and includes information on the physicochemical properties of the poisons, the frequency of such poisoning, a historical background, and a solid practical guide to diagnosis, treatment, and prognosis A vast amount of fact is compressed into a very reasonable and inexpensive space, and the topic is enlivened by many case-reports (models for any case summaries) A text of high literary merit is attractively interspersed with pithy comment The reader may enter Professor Polson's museum and admire the splash of blue from the stomach of a case of nitroprusside poisoning, or he may be led to speculate on the proposition that Eve, as depicted in an old fresco, was maintaining a certain posture more from *Amanita muscaria* poisoning than from modesty A nostalgic mention of a maiden aunt's cowslip wine is followed, however, by a stringent comment on the medicinal merits of alcohol

Industrial toxicology is not included as a general subject, and laboratory analytical procedures are not given, but these deliberate omissions do not detract in the slightest from the very great value of this book, and there are still reminders of simple tests for aspirin and carboxyhæmoglobin *Clinical Toxicology* is written for the practising clinician, but pathologists and those engaged in medicolegal affairs will also find it indispensable, and there can be few doctors who would not find in it something of absorbing interest

The Surgical Treatment of Scoliosis

LOUIS A GOLDSTEIN, M D, F.A C.S, associate clinical professor of orthopædic surgery, University of Rochester Medical Center Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1960 Pp 116 54*s*

IN this country surgical tuberculosis is now becoming a rare disease, and only one variety of gross spinal deformity is commonly encountered—that due to scoliosis And it must be admitted that, whatever strides orthopædic surgery may have made in other directions, there are still grave defects in our knowledge of this condition In its commonest form, we are still obliged to describe the disease as "idiopathic", and the second largest group of cases—the paralytic ones—are a sequel of poliomyelitis for which, of course, there is as yet no specific remedy That our ability to deal with scoliosis has increased at all is due to the publication, during the past thirty years, of several large series of cases treated in different ways This monograph from the Rochester Medical Center reviews Dr Goldstein's experiences in 65 cases

His management of a given case is based, as in other clinics, on the fairly accurate prognosis which is now possible An onset before the age of 10 years, and a principal curve in the thoracic segments, for instance, are usually serious portents When the deformity is greatest in the lumbar region, and develops shortly before skeletal growth ceases (i e, about 15), it seldom becomes at all severe or warrants interference

When treatment is indicated, Dr Goldstein obviously sides with those who believe that the only procedure which has a definite effect is operative fusion His book is a detailed guide to the assessment of patients, their preoperative care in turnbuckle plaster casts, and a fusion technique which involves the use of large quantities of fresh autogenous iliac bone. The operation should include many vertebræ (usually seven or eight) but can be completed in one stage A year must elapse before union is sound, and during eight months of this period the patient must be recumbent This is a widely accepted regime, and the author is to be commended for providing a handbook which will enable others to adopt it with success. He is also to be congratulated on achieving the results here described, with very few complications and no deaths One clue to this enviable record is provided by Vernon Thomas's appendix, which deals with anæsthesia in patients with scoliosis

A Guide to Antibiotic Therapy

HENRY WELCH, PH D New York Medical Encyclopedia. London Interscience Publishers 1959 Pp 69 23*s*

THIS book aims to give a profile of 31 antibiotics used in the treatment of human or animal infections, and to be a physician's ready reference It carries no text other than an introduction and foreword, thereafter each antibiotic is dealt with, in alphabetical order, from amphomycin to viomycin, in the form of a two-page chart In each chart organisms are arranged alphabetically, from actinomycetes to vibrio, followed by miscellaneous groups such as yeasts, rickettsiæ, viruses, and protozoa It is possible to read off the inhibitory concentrations of antibiotics to which the organisms are susceptible Next to each chart is a brief note on the indications for using the antibiotic, its side-effects, and available dosage forms

The editor and his assistants have undoubtedly amassed a large amount of useful information, but in this country the book is likely to have only a limited appeal It is too complicated for the average medical student Bacteriologists might occasionally refer to it, but the introduction and foreword do not recommend it to them but rather to practising physicians Only physicians who can think in bacteriological terms would really comprehend it quickly It is like a navigator's compass—an important instrument so long as you are a navigator and know how to use one

Vitamin B_{12}

E LESTER SMITH, D SC, F R S, senior biochemist, Glaxo Laboratories London Methuen New York John Wiley 1960 Pp 196 15*s*

THE author of this monograph, one of a series on biochemical subjects, must know as much as anyone about vitamin B_{12} and he has written a balanced review of the whole topic for "those who have neither time nor necessity to study it more extensively" It includes reference to all significant papers up to mid-1958 The greater part is naturally taken up with chemical matters, but it is remarkably easy reading The chapters on assay methods, the vitamin B_{12}-binding factor, and absorption, excretion, and distribution in the body are specially useful to the medical reader It is interesting to see that biochemists seem to have decided that B_{12}-binding capacity is *not* identical with intrinsic-factor activity, that oral doses of vitamin B_{12} over 50 µg are probably absorbed by direct diffusion independently of intrinsic factor, and that 75% of a parenteral dose of 1000 µg is excreted in the urine within 8 hours There are many facts like these to be found, and we do not know of a better introduction to the subject of vitamin B_{12} than this brief but informative book.

Encyclopædia of Urology—In reviewing (March 26) the first three volumes of this encyclopædia to appear, we mistakenly indicated that all sixteen volumes will be published in English, French, and German versions In fact each contributor writes in one of these languages, but there will be no translations It so happens that these first three volumes are all in English

THE LANCET

LONDON 9 APRIL 1960

Challenge to Southey

IF the last enemy is death, the second-last for many patients is massive œdema which defies such expedients as sodium restriction and the whole range of diuretics In such circumstances the temptation is to tackle the problem directly, by allowing the œdema fluid to gravitate into the legs and then letting it escape through Southey's tubes or the wounds of acupuncture Large amounts can often be drained off in this way, with relief of dyspnœa and sometimes a restored response to diuretic agents Drainage of œdema fluid has been enhanced by the use of modified Southey's tubes with lateral openings, and the risks of local infection can largely be met with modern antibiotics As the use of a procedure becomes more widespread, unexpected dangers sometimes come to light, and in this issue Dr VERE and Mr KING draw attention to untoward reactions which they observed on ten occasions in seven patients treated by acupuncture drainage of œdema fluid

Six of the patients had gross œdema due to chronic nephritis, and associated with significant hypoproteinæmia, the seventh patient had anasarca due to congestive heart-failure following pulmonary hypertension, and the plasma-proteins were "normal" The sequels to drainage included collapse, oliguria, shrunken veins, nausea, and postural hypotension, two patients had symptoms attributed to acute-on-chronic potassium depletion—abdominal distension with absent gut-sounds, and mental confusion Both these patients had electrocardiographic changes consistent with potassium depletion, and in one of them renal biopsy showed the vacuolar nephropathy characteristic of potassium depletion The clinical reaction was associated with a carefully observed sequence of biochemical changes The blood-urea rose in all patients, sometimes despite increased urea excretion The serum-sodium fell, while the serum-potassium rose, urinary sodium and potassium each fell during the period of drainage, though sometimes diuresis followed with increased loss of potassium The plasma-protein concentration and hæmatocrit percentage were increased Creatinine clearance commonly fell, but the urine formed was often of higher specific gravity than was usual for that patient. In three patients the amount of fluid removed was over 10 litres (in one patient nearly 66 litres), but similar reactions were seen after removal of much smaller amounts of fluid—around 5 litres

The precipitation of complex metabolic disturbances by the removal of a relatively small portion of a large accumulation of isotonic fluid may seem somewhat rather surprising Many of the features of the syndrome are explained by VERE and KING in terms of hypovolæmia, which in other contexts is known to produce the circulatory collapse, nausea, thirst, oliguria, and raised blood-urea found in these patients It is not easy to see why the lowered plasma-volume was not made up by entry of fluid from the considerable remaining depots of œdema fluid, but clearly the circulation in œdematous limbs is far from normal, and œdema fluid may be effectively out of reach of the general circulation On the basis of the low plasma-sodium and raised plasma-potassium, VERE and KING draw an analogy with the "reaction to injury"[1] The "reaction to injury", however, is usually associated with retention of sodium, whereas in these patients considerable amounts of sodium were inevitably withdrawn from the body In the search for parallels there comes to mind the low-salt syndrome of SCHROEDER,[2] in which collapse and extrarenal uræmia were induced by therapeutic sodium depletion, even when massive œdema persisted, and also the collapse which may follow abdominal paracentesis,[3] in which low plasma-sodium and raised plasma-potassium are also found The relevance of sodium depletion to the syndrome now described is shown by the improvement of symptoms when salt was ingested

Discussing the practical implications of their observations, VERE and KING suggest that drainage should be gradual and controlled by observations of the blood-pressure, plasma-protein, and hæmatocrit. Potassium supplements may be needed during the diuresis which may follow drainage, but the plasma-potassium should be controlled in patients with renal disease, especially as sodium depletion may diminish the output of potassium A rise in blood-urea during drainage of œdema does not necessarily indicate progression of renal disease while it may be due to low renal blood-flow, or to temporary renal damage from potassium depletion, it may also be of extrarenal origin, and disappear when the hypovolæmia is corrected

The hazards of removing œdema fluid rapidly have been described in Germany and Poland, but this seems to be the first thorough account in the English language Since six of the seven patients described had both hypoproteinæmia and pre-existing renal damage, it may not be possible to apply these findings directly to the more common problem of congestive cardiac failure Further observations during mechanical drainage in patients without hypoproteinæmia or renal damage should clear up this point, now that this interesting syndrome has been delineated

Red-cell Regulators

THE regulation of the production and maturation of red blood-cells by humoral factors has been investigated and discussed for over fifty years In the past few years experiments reported from several laboratories have again suggested the existence of such humoral stimulation BORSOOK et al[1] made rabbits anæmic by giving them the hæmolysing drug, phenylhydrazine They prepared from the plasma of the anæmic rabbits a protein-free extract which they injected daily into healthy young rats, after about a week the hæmoglobin level and the hæmatocrit began to rise, and this increase continued as long as the injections were kept up For example, in one rat with an initial hæmoglobin of 14 3 g per 100 ml, when such injections were being given the level rose week by week to 15 4, 16 5, 17 4, and 18 1 g per 100 ml The erythropoietic factor was not destroyed by boiling for fifteen minutes at pH 5 5—a procedure that coagulated nearly all the plasma-protein In a later study[2] this group of workers used reticulocytosis in the adult mouse and the uptake of ^{59}Fe in the blood of starved rats as indicators of the erythropoietic activity of the plasma of these anæmic rabbits They found that heat treatment was needed to destroy the antigenicity of the plasma-proteins but that milder treatment, leaving about 20% of protein, still gave fractions with full erythropoietic activity By fractionation methods, including zone electrophoresis, they were able to concentrate the erythropoietic fraction but were not able to separate it from protein material

LINMAN et al[3] used similar methods to determine whether an erythropoietic-stimulating factor was present in the plasma of patients with primary or secondary polycythæmia They prepared a non-antigenic extract by boiling the plasma at pH 5 5 and filtering, and then by treatment with perchloric acid they obtained an extract which they considered to be protein-free[4] The protein-free extracts were injected into normal rats Those from patients with either primary or secondary polycythæmia produced reticulocytosis, a rise in the red-cell count in the peripheral blood, and increased erythropoietic activity in the bone-marrow, these stimulatory effects persisted so long as daily plasma injections were continued and ceased quickly when injections were no longer given LINMAN et al concluded that these results confirmed the existence of a humoral erythropoietic factor in man It could be argued that in the patients with secondary polycythæmia hypoxia had stimulated the production of the erythropoietic agent, and ERSLEV[5] has shown that tissue-oxygen concentration rather than arterial oxygen tension is the important factor But in polycythæmia vera there is no evidence of decreased tissue-oxygen tension, and LINMAN et al postulate a " derangement of physiologic regulation of erythropoiesis " The site of erythropoietin production is also uncertain Although polycythæmia has been observed in association with lesions in the region of the pituitary and midbrain, LINMAN et al doubt whether the plasma factor is of pituitary origin since removal of the pituitary does not prevent erythropoietic stimulation by hypoxia Nor does the site seem to be the bone-marrow, since neither X rays nor nitrogen mustard[6] reduce its effect

Further work by LINMAN et al[7] showed that the red cell-stimulating factor of plasma could be subdivided into two factors with different actions The first factor is thermostable and ether-soluble, it stimulates division of erythroblasts but does not increase hæmoglobin synthesis The second factor is relatively thermostable and is insoluble in ether, it enhances hæmoglobin synthesis but does not stimulate erythroblast division. An effect similar to that of the first of these factors was obtained in rats that had been given " batyl alcohol "[8] This glyceryl ether was isolated by SANDLER[9] from an extract of yellow bone-marrow of cattle—an extract that stimulated erythropoiesis in normal rats and in rats made anæmic by administration of benzene Consequently LINMAN et al suggest that the red-cell-stimulating substance they are studying may be related to batyl alcohol, and batyl alcohol has been said to produce reticulocytosis in man In later experiments LINMAN et al[10] took plasma from patients with polycythæmia vera both in clinical relapse and in therapeutic remission induced by radioactive phosphorus, and subjected the samples to the treatment necessary to separate the two erythropoietic factors When the extracts were injected into rats daily for fourteen days, both erythropoiesis and hæmoglobin formation were increased In polycythæmia vera in man granulocytes and platelets are often increased, and LINMAN et al showed that in somewhat larger amounts the plasma extracts produced such increases in rats an extract containing the ether-soluble factor 1 increased platelets, an extract containing the thermostable factor 2 increased neutrophil polymorphs and platelets They therefore conclude that derangement of the regulatory role of these humoral factors may be responsible for all aspects of the blood changes in polycythæmia vera, but they cannot suggest the cause of the derangement

Yet another facet of this problem has been explored by OSNES,[11] who has described work on an erythropoietic principle produced in the kidney In one set of experiments on mice, the left kidney was irradiated so as to produce a condition like glomerulonephritis, the right kidney was removed in one group and was rendered hydronephrotic by ligature of the ureter in a second group, and in a third group the excretory function was neutralised by allowing the urine to drain into the peritoneal cavity These procedures caused a similar degree of uræmia in all three groups, but anæmia was evere in the first group only, was moderate in the econd, and was absent in the third Osnes interpreted hese results as showing that the amount of kidney issue determines the degree of anæmia, and he confirmed this by other experiments, for instance, daily bleeding caused a rise of reticulocytes in normal mice, but in others in which one and a half kidneys had been removed there was hardly any reticulocyte response The kidney erythropoietic principle was found in protein-free ultrafiltrates and was thermolabile Osnes reminds us that many experiments have shown the presence of a different red-cell stimulator in mice serum from mice that have been bled repeatedly will cause reticulocytosis in normal mice, into which it is injected, and if the injections are repeated, polycythæmia will result. This factor, erythropoietin, seems to be a protein or a protein-bound substance. But injections of serum with erythropoietin activity will *not* cause reticulocytosis in nephritic mice, and on the other hand serum from bled nephritic mice does show erythropoietin activity Thus the erythropoietic kidney principle and the so-called erythropoietin seem to be quite distinct

[11] Osnes, S *Brit med J* 1959, ii, 650

Using as test animals normal and nephritic mice Osnes tested suitably prepared sera from human subjects Serum from a patient after severe hæmorrhage, from one with sideropenic anæmia, and from one with pernicious anæmia all produced reticulocytosis in normal and nephritic mice, so both factors were present in their sera Serum from patients with chronic nephritis and anæmia produced reticulocytosis in normal but not in nephritic mice, so the kidney principle was lacking in these patients Similar results were obtained in patients with ulcerative colitis and rheumatoid arthritis, and in a patient with polycythæmia and renal complications Jones et al [12] have described two cases of polycythæmia—one a patient with hydronephrosis and the other with a polycystic kidney—in which nephrectomy restored plasma-erythropoietin levels, previously raised, to normal and ended the polycythæmia

A different approach again is that of Feodorov et al [13] in Moscow They describe the properties of a hæmopoietic factor found in gastric juice—a factor quite distinct from the gastric "intrinsic factor" which is so important in the ætiology of pernicious anæmia Feodorov's factor, which is thermolabile and dialysable, is detected by its ability to stimulate mitotic activity and formation of hæmoglobin in marrow-cultures It is present in neutralised gastric juice, and in both man and dog it is produced in the fundus of the stomach It is not found in the gastric juice of patients with pernicious anæmia, in other anæmias, including aplastic anæmia, it is present, but it can be depleted by repeated bleedings, in polycythæmia the factor is apparently increased

All this work, and that of several others, amounts to an accumulating body of experimental evidence of the existence of humoral regulators of red-cell production and maturation If we could concentrate or isolate these in a form that could be handled, they might prove valuable in the treatment of anæmias that are not due to deficiencies of essential red-cell constituents or to hæmolysis Indeed Osnes claims that he has prevented the development of anæmia in nephritic mice by administration of active material The reason why this work has so far roused little enthusiasm among clinical hæmatologists is undoubtedly that almost all the work has been carried out in mice, rats, and rabbits, and mice and rats are the test animals for detecting these substances Many promising lines of work based on experiments in rodents have petered out when applied to man or even to other mammals The hæmopoietic system of rodents seems to have different reactions, and the cells often have different functions from those of man and other animals But, despite some contradictions, the evidence from rodent experiments does begin to hang together quite satisfactorily, and the attempt to apply the results elsewhere may be worth making

Annotations

ADRENALINE AND NORADRENALINE METABOLISM

Although the pressor activity of adrenal medullary extract was first demonstrated sixty-five years ago [1] many aspects of the metabolism and action of adrenaline and related catechol amines have only recently been brought to light The necessity for a further symposium on adrenergic mechanisms (held in London on March 28 and 29 [2]) only eighteen months after a similar meeting in the U S A [3] reflects the increased tempo of research

One aspect on which much progress has been made—namely, the fate of adrenaline and noradrenaline in the body—was discussed in London by Dr J Axelrod [4] When we last reviewed this subject,[5] details of the new metabolic pathways unveiled by the identification of 3-methoxy-4-hydroxymandelic acid (V M A) as an important metabolite [6] were still obscure thus the relative magnitude of O-methylation and amine oxidation in the primary inactivation of adrenaline and noradrenaline had still to be established Axelrod spoke of data on this point which had been obtained by means of an ingenious technique devised by Kopin [7] By assaying the ratios of the isotopes in excreted metabolites after simultaneous injection of ^{3}H-labelled adrenaline and ^{14}C-labelled 3-methoxy-adrenaline in man, it was calculated that about 68% of administered adrenaline is first O-methylated and about 23% deaminated before O-methylation That O-methylation is the more important mode of primary inactivation is confirmed in retrospect by the work of Bacq [8] In laboratory animals he obtained physiological potentiation of adrenaline action with pyrogallol, a member of a group of compounds which has since been shown to inhibit the enzyme responsible for O-methylation[9–11]—the ubiquitous catechol O-methyltransferase[12] On the other hand, inactivation of monoamine oxidase, for which adrenaline is a substrate,[13] does *not alter the in-vivo response to administration* of catechol amines[14] Inactivation of adrenaline is facilitated, in the mouse at least, by reserpine, chlorpromazine, imipramine, and amphetamine,[15] which are widely used in psychiatric practice

Axelrod stated that in man about 45% of the final products of adrenaline and noradrenaline metabolism are excreted in the urine as free V M A —which conforms with the findings of other workers[16 17]—and about an equal amount as O-methylated adrenaline and noradrenaline, conjugated as sulphate derivatives Smaller amounts of free and conjugated adrenaline and noradrenaline, of dihydroxy-mandelic acid,[17] and of a newly discovered metabolite—3-methoxy-4-hydroxphenylglycol[18 19]—are also found in the urine The clinical usefulness of V M A estimation in the diagnosis of phæochromocytoma has now been recognised This estimation was especially helpful in 2 cases in which V M A output was increased but excretion of catechol amines was normal[20 21]

Sandler and Ruthven[20 23] have described a quantitative colorimetric method for estimation of V M A in urine which should go far towards bringing the diagnosis of *phæochromocytoma within the scope of the routine* clinical laboratory Comparable methods for other metabolites will surely follow

AIRBORNE BEHAVIOUR

THERE is a certain sameness about the pictorial advertisements for the great airlines All the aeroplanes are half empty, and such passengers as are shown are honeymoon couples or handsome and muscular " executives " (whatever an executive is) in polite conversation what time elegant ladies in uniform offer a choice of expensive groceries We have probably been unlucky, but our experience does not agree with this picture precisely, and we were glad, therefore, to read an objective analysis of the behaviour of air passengers based on the answers to a questionary completed by the stewardesses on the airlines serving Los Angeles[24]

The first conclusion is that most airline passengers are well behaved It is true that young men travelling in groups tend to raise hell, but, as this report says, most passengers behave in the air much as they do on the ground *Passengers tend to be unduly dependent*—i e, they ask silly questions Men seem to behave rather worse than women, and a major complaint is that they do not get enough to drink 156 displays of extreme emotion were classified as fear (67), anger (57) sorrow (11), and other (21) He must be a very seasoned traveller who leaves the ground and meets it again without a single flutter of his diaphragm, but the middle-aged man who leapt from an emergency exit as the 'plane was about to take off must have been excessively anxious What is really surprising *is how cross the passengers get* 19 cases, involving cursing and fighting, were due to drink which the passenger had brought aboard either in him or on him 16 passengers said that the airline had treated them badly these are not shown in the advertisements 12 had " hostile personality traits ", and 10 were " personally frustrated " The best example of these last unfortunates was the poor chap who had booked on another plane and (by his own fault) lost his seat he had lost his luggage, his wife had left him, his secretary was pregnant, he had not slept for four nights Was he wild?

Almost as *interesting is the analysis of the action taken* by the stewardesses to stifle excessive emotion of all kinds They reason, distract, or threaten, but the ultimate sanction is to call the Captain Despite all this odd behaviour no-one has been made to walk the plank.

PULMONARY COMPLICATIONS OF RHEUMATOID ARTHRITIS

VARIOUS pulmonary and pleural complications arise in the course of rheumatoid arthritis, but most of them do not seem to differ from the respiratory disorders seen in the ordinary run of general hospital admissions In a large controlled study of hospital cases Aronoff et al[1] found no lung lesion characteristic of rheumatoid arthritis There are nevertheless grounds for believing that rheumatoid arthritis can in fact cause or modify certain pulmonary lesions

Firstly, histologically typical rheumatoid nodules sometimes appear in the lungs,[2 3] and they may be widely disseminated through the lungs, pleura, pericardium, and heart, as well as in the subcutaneous tissue and muscles *Secondly (and the only significant association between* rheumatoid arthritis and lung disease so far demonstrated on epidemiological grounds) are the nodular changes described by Caplan[4] in the lungs of coalminers with rheumatoid arthritis—lesions seen also in occupations involving other dust hazards This form of nodular fibrosis, consisting of many well-defined rounded shadows on a background of slight pneumoconiosis, is often distinguishable from progressive massive fibrosis, and as Miall[5] has suggested, it is probably a particular type of tissue reaction to dust and tuberculosis in the lungs of miners who are predisposed to rheumatoid arthritis Thirdly, there may develop diffuse lung changes in the form of a chronic fibrosing pneumonitis, first described in association with rheumatoid arthritis by Ellman and Ball[6] Radiographs show diffuse reticular shadows which are not in themselves specific, and, as Scadding[7] pointed out, it is hard to be sure whether the changes are due to the same disease process as the rheumatoid arthritis or to some other cause It is presumably progression of the interstitial fibrosis which leads to the appearance of " honeycomb lung," also noted in association with rheumatoid arthritis[8] Fourthly, the generalised arteritis of rheumatoid disease may involve pulmonary vessels,[9] and has been hown to cause pulmonary hypertension[10], and it is of terest that Wade and Ball,[11] in their series of patients ith idiopathic pulmonary hypertension, found some with ulmonary arteritis and a positive Rose-Waaler test but no inically evident rheumatoid arthritis Finally, there is the omplication of pleural effusion, with or without underying parenchymatous lung lesions, usually appearing hortly after the onset of rheumatoid arthritis or accomanying an exacerbation of the disease[12 13] It seems to be emarkable for its predominance in males, in contrast to he increased incidence of rheumatoid arthritis itself in women.

Pleural effusion is the principal feature noted by Horler nd Thompson[14] in an extensive review of pleural and pulmonary complications of rheumatoid arthritis in 180 patients They found that 9 patients, 8 of them males, had a pleural effusion for which no cause could be found other than rheumatoid disease, though they emphasise the importance of excluding other connective tissue disorders, tuberculosis, and malignant disease. The pleural fluids were clear and pale yellow and had the characters of an inflammatory exudate with high protein content and a varying proportion of neutrophils and lymphocytes 2 of the patients also had coincident parenchymatous lung lesions, in 1 nodular and in the other diffuse and fibrotic. Another male patient without pleural effusion showed the radiological appearance of "honeycomb lung" In most instances the effusion appeared with an acute febrile respiratory illness related to the onset of arthritis, though in some the effusion preceded the arthritis, and it is perhaps arguable that the relationship was no more than that of a precipitating factor The series nevertheless gives convincing additional evidence that rheumatoid pleural effusion is a clinical entity

TREATMENT OF TRACHOMA

THE special reports of the World Health Organisation published in 1952 and 1956[15] established the value of the tetracyclines in the treatment of trachoma, particularly as a mass measure in trachomatous countries A valuable additional study has now been made by Reinhards et al,[16] who report an extensive and systematic study on the use of chlortetracycline in schoolchildren in Morocco They report on three distinct surveys, each sufficiently extensive to give conclusive results

In the first a group of 3828 trachomatous children in the schools of Marrakech were treated according to the schedule recommended in the 1952 report Chlortetracycline was given in the form of 1% ointment three times daily for sixty consecutive working days The different stages of trachoma were fully represented in this group of children, and 59 6% of the active cases were found to be clinically cured at the end of the first follow-up period some seven months after the completion of treatment, in a small proportion the result was indefinite The rate of cure was as high as 72 8% in trachoma stage I, but was distinctly lower when gross complications were already present The children needing further treatment were given a second course a year later, sulphonamides by mouth also being used No less than 77 9% of those who underwent a second course were clinically cured at the end of the treatment, leaving a relatively small group in which there was either failure or reinfection It became clear during this investigation that indefinite results were in fact cures, for the persistence of fine papillary hypertrophy in the absence of corneal lesions may be regarded as compatible with clinical cure It also became clear that scarring of the conjunctiva, which in days gone by was deliberately produced to cure trachoma, was not a necessary feature of cure by specific measures—a point made by early observers of specific therapy of trachoma Thus Sorsby[17] in 1945 stressed that with sulphonamide therapy scarring was very slight, and the tarsal conjunctiva remained remarkably supple and showed a pearly tinge Reviewing the experience of this first survey as a whole, Reinhards et al conclude that a course of treatment such as the one they used, with a second course in the failures, gives almost complete control of trachoma in schoolchildren, more than 98% of children were cured

These workers next dealt, in 1955 and 1956, with 4136 trachomatous children in the schools of Meknes, using three different schedules of treatment with the object of determining the minimum effective course One group of children was treated according to the standard schedule—i e, 1% chlortetracycline ointment instilled three times daily for sixty consecutive working days (on five days a week for twelve weeks) A second group had the same treatment but only twice daily, and a third group had the same ointment twice daily on three consecutive days, repeated every four weeks over twenty weeks—i e., six cycles of treatment In the three groups the percentages of cures were very much the same 69 6, 69 6, and 71 1 The proportion of failures was also very much the same 7 5%, 8 5%, and 8 2% In these series, as in the first survey, there was a small group of relapses (estimated at 1 1% of cases) and of reinfection (not more than 0 7%) This survey showed that the less exacting modes of treatment were as adequate as more intensive methods Apparently nothing is lost by reducing the application of ointment to twice a day instead of the original three times a day suggested in 1952 and 1956, and there is apparently no need to maintain treatment continuously for sixty days two applications on three consecutive days each month for six months is equally effective.

In the third survey, covering 1167 trachomatous children in 1957–58 in schools of the Tiznit province of Morocco, the short-term intermittent treatment was applied in order to determine whether under rural conditions in southern Morocco, where secondary infection is frequent, such treatment was as effective as in the towns It was found to be so

This careful analysis, based on thousands of cases, is itself part of a very much larger scheme made possible by the simplicity of the measures now used, in 1958 altogether 263,000 children were treated in Morocco, and the target figures for 1959 and 1960 were 350,000 and 400,000—an extension which means covering the whole country Reinhards and his associates also report some personal communications from other countries on the value of short-term intermittent treatment, these results are all of the same order as those they obtained themselves Several issues still remain the minimum requisite treatment of antibiotics probably varies from country to country, the optimum interval between cycles of treatment has still to be determined, and clearly where distortion of the lids and trichiasis are present surgical correction is still imperative Whether drugs other than chlortetracycline are equally effective is uncertain, but Reinhards et al cite J G Scott as having obtained satisfactory results from chloramphenicol applied intermittently for three consecutive days each month for a year in schoolchildren in South Africa

[17] Sorsby, A *Brit J Ophthal* 1945, 29, 98

The short-term intermittent treatment of trachoma advocated in this report is a radical break from the traditional methods, which involved years of constant treatment, and much interest attaches to the suggestion by Reinhards et al that intermittent treatment is effective because it spreads the therapy over different phases of relative activity and non-activity of the virus Now that the virus of trachoma has been isolated—and apparently established from the increasing number of successful inoculations in volunteers[18]—this hypothesis and much else besides has become open to experimental trial

ALCOHOLIC *v* NON-ALCOHOLIC CIRRHOSIS

It has long been recognised that hepatic cirrhosis is not a disease entity but the scarred stage resulting from many different pathological processes, themselves the result of different ætiological factors[19] Nevertheless, in some patients the hepatic disease is clearly part of a recognisable disease entity, such as hæmochromatosis or Wilson's disease In others, gross overindulgence in alcohol plays a significant but ill-understood part, while in yet others no correlation can be established and the process can at present only be regarded as cryptogenic These two forms of the disease constitute the great majority of the cases in Great Britain and the U S A , but their relative incidence differs strikingly between the two countries A group of 35 alcoholic cirrhotics in the Boston City Hospital has now been carefully compared with a group of 35 non-alcoholic cirrhotics in Hammersmith Hospital, London[20]

Striking differences between the two groups of patients were revealed Thus males were twice as numerous as females among the alcoholics, but only half as numerous in the other group Malnutrition, and especially a deficiency of dietary proteins, was clearly established in 26 of the Boston patients but was insignificant among the patients at Hammersmith Clinically the outstanding features of the alcoholic patients were those attributable to hepatic failure, such as jaundice and hepatomegaly, in contrast to the non-alcoholic group in which portal hypertension and its associated features of splenomegaly and gastrointestinal hæmorrhage were predominant Other features related in some obscure way to hepatic function, such as gynæcomastia, parotid-gland enlargement, and Dupuytren's contracture, were found exclusively in the alcoholic patients, while leucopenia and thrombocytopenia were almost confined to the non-alcoholics

The differences in the morbid anatomy of the liver were equally striking and consistent between the two groups In alcoholic cirrhosis the liver was enlarged, but in the non-alcoholics small mean weights 1806 and 1055 g , respectively On the other hand the regeneration nodules in the non-alcoholic patients were almost three times the size of those in the alcoholics diameters 9 0 and 3 5 mm , respectively Fatty infiltration, a conspicuous feature of the alcoholic liver both at biopsy and at necropsy, was virtually absent in the non-alcoholics These and other changes indicate that the cirrhotic liver in alcoholic patients typically shows the features of diffuse hepatic fibrosis, while that in the non-alcoholic patients conforms to the picture of postnecrotic scarring with nodular hyperplasia

The results of this detailed study have thus convincingly shown that the cirrhosis associated with alcoholism is *in general clinically and anatomically distinguishable* from cryptogenic cirrhosis Unfortunately, the study has contributed little to our knowledge of the pathogenesis of the former or the ætiology of the latter The findings do, however, accord with the view that fatty infiltration is a stage in the development of alcoholic cirrhosis, and that nutritional deficiency is not unimportant in its pathogenesis[21] It is also apparent that at least in this country alcoholism is not the main cause of cirrhosis, but whether the main cause is the virus of infective hepatitis is uncertain

The most important conclusion to be derived from this study is that the prognosis differs between the two types of disease the outlook of the alcoholic is far better, especially if the patient can be induced to improve his nutrition and curtail his consumption of alcohol

EVOLUTION OF PSYCHIATRIC RESEARCH

The extraordinary rate of progress of psychopharmacology and neuropharmacology over the past ten years indicates that psychiatry has entered on what Rostow might call the " take-off " phase of development Recent work has taken two complementary forms The first has been the direct investigation of the metabolism of psychotic people in an attempt to find abnormalities of various kinds, and some rather patchy progress has been made in this direction The second has been the study of basic neurochemical and neurophysiological mechanisms which may underlie psychoses, at present this is likely to prove the more fruitful course This work, in turn, takes two forms The first is the careful comparison of the " model " psychoses with natural psychoses by objective psychological and psychopharmacological methods The second is investigation of the mode of action of the drugs producing a " model " psychosis

We still know very little of how drugs such as lysergic acid diethylamide (L S D), mescaline, and amphetamine act at biochemical, physiological, and pharmacological levels We do not know the metabolic fate of the bulk of the mescaline that enters the body, we do not know whether it acts on the brain directly or through some metabolite, or whether it interferes with the metabolism of some other substance in the body, we know very little about its action on cerebral enzymes, neuronal activity, synaptic transmission, and the electrical activity of the brain, and only the initial phases of its structure/activity relationship have been worked out Very little more is known of the mode of action of L S D An excellent review published by the World Health Organisation[22] includes an article by E Jacobsen, who surveys the actions and interactions of ataractic and hallucinogenic drugs (Two appendices give useful lists of these drugs and their structural formulæ) The clinical use of ataractic drugs is discussed by N S Klein, and of L S D by R A Sandison.

THE THIRD PHASE IN GERIATRIC MEDICINE

DESIGN AND PURPOSE OF A HOSPITAL GERIATRIC DEPARTMENT *

G F ADAMS
M D Belf, M.R C P
PHYSICIAN, WAKEHURST HOUSE, BELFAST CITY HOSPITAL

OVER the centuries primitive superstition has given way to a concept of disease due to natural causes, and on this basis, by application of the scientific method, successive generations have evolved the present system of clinical practice This system, however, was becoming overweighted by highly technical methods of inquiry and treatment, especially in clinical teaching and research, while the wider aspects of health and sickness in the community and the effect of social and occupational factors were being neglected One of the problems of our generation is to define " the precise relation of medical practice to society ", and Wakehurst House is an expression of a new medical attitude towards old people Since 1948 by renovation and new building it has become a rehabilitation unit specifically designed for them It is not the result of chance development, but is founded on firm beliefs

SOME PRINCIPLES

Time and Space for Patients

The first of these is that old people deserve and need something better than the care they were offered by the old dual hospital system The tradition then was that teaching and voluntary hospitals catered for a quick turnover of emergency cases and acute illnesses, leaving municipal or poor-law hospitals to look after the destitute and chronic sick But the general hospitals were ill equipped to meet the needs of old people, who could not attain the speed and extent of recovery expected in general wards Inevitably many of them were moved prematurely to the chronic hospital wards where they were deprived of the encouragement and facilities needed for restoration of activity

The modern geriatric unit bridges the gap between general and chronic wards, and is designed to give older people the rehabilitation after illness which Rusk (1959) has described as " the third phase of medicine " The unit seeks to eliminate physical disability, or reduce it as much as possible, and to retrain the patient " to live and to work within the limits of his disability but to the hilt of his capabilities " In general medical or surgical wards the scope for this work is limited because there the treatment of acute illness and emergencies, especially in young people, must have priority over the painfully slow process of rehabilitation in old age

There is not enough space for chairs, walking-aids, and exercise Most of the physiotherapy and exercise for elderly patients must be given in the ward, because all the old people need some, and it would waste time and deprive the ward of much-needed stimulus to transport all " up " patients to a physiotherapy department These points, especially space, were considered in the design of our new wing

Equipment for Nurses

The second belief underlying the design of our unit is the care of hospital long-stay patients This is essentially a nursing responsibility, and it should be shared by all nurses of all hospitals There is no virtue in the custom of disowning responsibility for one's homeless failures, and in Wakehurst House we have planned the new wards so that each sister carries her share of long-stay patients—a minimum of 40% If the sister has a proper staff-patient ratio, she can manage this efficiently and supervise the nursing of acute illness and rehabilitation as well It is only when she is overburdened with too many incontinent, difficult hard-core patients, or when she is deprived of her essential minimum of trained staff, that proper standards cannot be maintained, the ward gets out of hand, and nursing in it becomes unpopular

We believe the success or failure of the work of a geriatric unit depends so much on the nurses that they should have the best possible facilities for their work Every effort has been made to provide these in planning the layout of the ward-space, annexes, and clinical rooms, and by equipment and labour-saving devices

The beds are adjustable to a convenient height, or to a low level for convalescent patients to get in and out safely Three-quarter-length cot-sides, a urine-bottle holder, a simple over-bed rail for physiotherapy equipment, lockers, and a lifting-chair were designed to our specifications Cantilever bed-tables, cot-tables, and chairs were selected for special needs The linen and laundry arrangements for incontinent invalids are not yet complete, but they include a central linen pool, a foul-wash unit, terry-towelling blankets, and trolleys designed for laundry-bags There are also trolleys for " backs and dressings " and bedpan rounds

RENOVATION

The old chronic wards, where the unit was started in 1948 (Adams 1949) each held 60–65 beds in four rows They stood in two 3-storey blocks connected by a long corridor on the ground floor By 1951, however, the unit, with only 240 beds, was coping successfully with almost twice the intake of patients achieved before 1948 and it was possible to close one ward for renovation

The old wards were divided by a wall into a large upper section of approximately three-fifths of the length, and a lower two-fifths where we segregated the incontinent or confused long-stay invalids The upper sections of two of the wards became rehabilitation units for patients with locomotor disorders such as hemiplegia, fractures, or arthritis In two of the other wards these upper sections became admission units for patients with medical ailments needing investigation and treatment, but less specialised physiotherapy and exercise than those in the rehabilitation wards—e g , cardiac failure, respiratory disease, anæmia, malnutrition and debility, or early mental illness The rest of the beds in these wards were used for long-stay patients, or for infirm old people awaiting discharge to welfare homes It soon became clear that fewer male than female beds were necessary, and we now have a ratio of 2 to 1 in favour of the women.

The first ward renovation (fig 1) was completed in 1952 and cost £4400, or a little more than £100 a bed

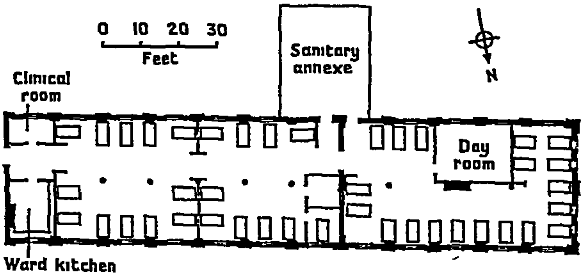

Fig 1—Renovated ward.

---

*Based on a paper read to the British Geriatrics Society, Sept. 24, 1959

The narrow wooden windows were replaced with modern steel windows admitting much more light, lino-tiles were laid on the old scrubbed floors, new central lighting and bed lights were installed, the ward kitchen was renovated A glazed steel partition formed a sister's station in the centre of the ward alongside a single-bed cubicle, a clinical side-room, and another partition at the lower end of the ward formed a dayroom The upper end of the ward was divided so that there were two subsections, with properly spaced beds around an open central floor-space where parallel bars and other facilities for exercise could be provided The old black hospital beds were fitted with 'Homa' casters and cream stove-enamelled, new lockers, bed tables, and easy chairs were provided

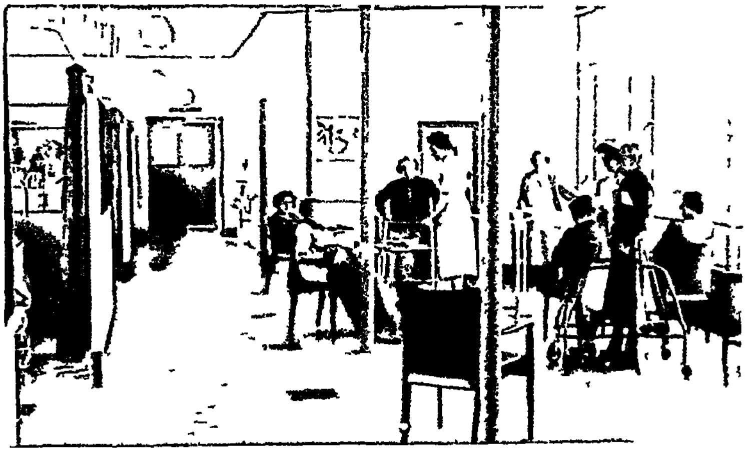

Photo-Reportage

Fig 3—Exercise bay in rehabilitation ward with curtained cubicles on the left.

A second rehabilitation ward was renovated the following year, and a second pair of wards, with partitioned admission beds for the "medical" patients mentioned above, a little later The new steel and concrete staircases and additional fire-escapes provided for the new wing enabled us to reoccupy a top floor which had had to be closed to comply with fire regulations This was reconstructed as a long-stay ward with men at one end and women at the other A "holding unit" of 4 beds in two pairs in the centre of the ward was added for men or women according to the needs of the waiting-list The demand for beds for men falls in the summer and rises again in the winter

REBUILDING

When we came to build a new wing of 80 beds in 1952 we were able to apply the principles outlined earlier and the experience gained in the rehabilitation wards which it was intended to replace It was agreed that it should be a 3-storey building, carrying two wards on the upper floors and providing administrative offices and outpatient facilities on the ground floor The architect, Mr Val Smyth, carried out an intensive work-study for three months, watching all activities from the care of the patient to ward-cleaning and the disposal of laundry or rubbish As a result the design of the wards and equipment has proved very satisfactory in practice Our only regret is that the physiotherapy and occupational-therapy departments are divided by a corridor, for at times this is an insuperable barrier to a handicapped invalid trying to move from one to the other Their work is so closely integrated that they should be divided only by a semi-permeable membrane which will readily encourage osmosis of patients and staff

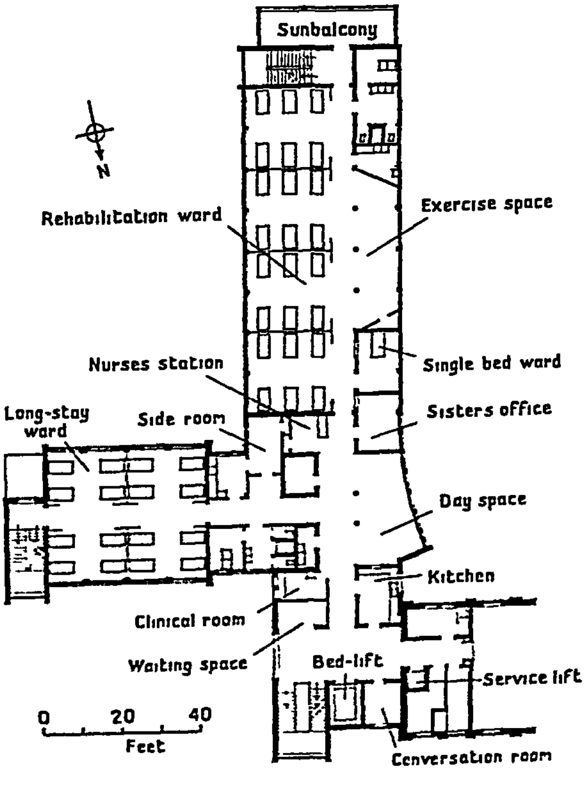

Fig 2—Plan of new wing

We had found, in the old wards, that disturbed patients in the lower end could upset the peace of mind of those in the rehabilitation section

The new wards (fig 2) were therefore designed in a reversed L shape, the smaller arm of the L being a self-contained long-stay unit of 16 beds, with its own annexe, sluice-room, and a large side-room or "clyster room" into which a patient can be wheeled in bed for an enema. The longer arm of the L is the rehabilitation ward (fig 3) with four 6-bed bays to one side, separated by 6 ft wooden partitions carried 12 in. clear of the floor and glazed to a low level, so that as many patients as possible are under observation from the nurses' station at the angle of the L On the other side of the ward is a large exercise space (fig 3) with built-in parallel bars, flanked by the annexe and sluice-room, a single-bed ward, and the sister's office Instead of a day-room, which tends to be boxed-in and of little general use, the angle of the L carried an attractive open day-space beside the kitchen at the entrance to the ward, also under direct observation from the nurse's station.

A medicine cupboard was built into the nurse's station with a small sink and work-top, and a separate clinical room with sterilising equipment is provided The waiting space outside the ward on the landing, a "conversation room" nearby, and the lifts, serve the new ward and also one of the renovated old wards adjoining it, on each of the upper floors The conversation room is available to patients who wish to have privacy for a discussion with relatives, clergymen, or the almoner A convertible bed-settee in it allows relatives to stay overnight with a critically ill patient

Thus the unit has seven 40-bed wards, six with single-bed cubicles, providing now a total of 286 beds, about 65 of them "active" and the remainder long-stay Two specially built wards provide 25 beds for rehabilitation and 16 beds for long-stay care of elderly men and women. Two other wards each provide 8 or 10 beds for male and female general medical admissions. All the remaining beds are long-stay—giving ratios of $3^1/_2$ long-stay to each active bed, and of 2 female to each male bed.

PURPOSE OF A GERIATRIC UNIT

Between 1948 and 1958 we admitted each year an average of 650 patients of an average age of seventy-six. We have a turnover of 3 patients a bed per year compared with 1 formerly, which is of course a vast saving in costs. 55% were discharged to home or residential care with support of domiciliary or outpatient services, 5% to institutional care, and 25% died within a year, 15% needed long-stay hospital care.

Two-thirds of our patients are admitted directly from their homes, referred by their family doctors for emergency admission, for rehabilitation, or for long-stay care (including terminal illness). Emergencies are admitted if a bed is free, or referred to the general wards if not and if the doctor cannot wait one or two days. Other new patients are visited by a doctor and an almoner from Wakehurst House, and according to this medical-social assessment are added to one of two waiting-lists.

The first is for patients with acute or potentially remediable illnesses, and for them admission can usually be arranged within two days or at worst within a week. The second is a list of long-stay patients who are often admitted within a week or ten days, and seldom wait more than six to eight weeks. These waiting-times are relatively short because they apply only to patients awaiting admission from their homes. Transfers from other hospital wards may have to wait longer, especially for long-stay care, and patients in terminal illness are not transferred at all because priority must go to those in difficulty at home. Patients' names are not added to the lists unless they are to be admitted, the lists are constantly under review. They usually carry 30–60 names, and women almost always exceed men by 3 to 1. Short spells of intermittent admission are arranged with the relatives of as many long-stay patients as possible, and the names of some of these recur constantly on the waiting-list.

Wakehurst House serves an industrial area with a population of 500,000, and apart from beds in some homes run by voluntary agencies there are only another 90 hospital beds in the area set aside for patients in terminal illness or prolonged chronic invalidism. The ratio of all hospital geriatric and long-stay beds to population in the area, therefore, is less than 0·7 per 1000, and not enough for an area of this size. More beds are needed for long-stay patients, but not a great many, for existing needs are being met fairly well, except during the winter. The main need for more beds is to relieve the disproportionate load of long-stay nursing care carried by the unit, and the number of extra beds is less important than how they are to be staffed. The problem is not one of bricks and mortar, but of nurses.

Each student nurse from the training-school of the Belfast City Hospital spends some months in the geriatric wards. Within the limits of the block-system of training, the 96-hour fortnight, leave, and sickness, we have aimed at staff-patient ratios of 1 to 2 on the rehabilitation wards, and 1 to 3 on long-stay wards. The rehabilitation ward staff carries a 30% "dilution" of trained orderlies, and the long-stay wards about 40%. An assistant-nurse training-school recently started will modify this in time, but experience suggests that older recruits to assistant-nurse training find the nursing care in the long-stay wards too heavy.

Efforts have been made to classify chronic invalids by defining their nursing needs as "simple" or "skilled". This implies an inferior standard of nursing for some patients which is unsound, and unacceptable. There are two kinds of bedridden chronic invalids who are homeless or need institutional care: (1) those who are rational, not incontinent, and who need personal service, that is, domestic care, and (2) those who are confused, and incontinent, or approaching terminal illness, who need nursing care. In time the first group will surely be accepted as residents in our welfare homes. The second group, the hard core of our failures, need hospital care. The nursing they need is skilled work worthy of the best of our nurses, and only people with second-hand knowledge of the job could regard it as anything less. It seems to me that to obtain this skilled nursing, to spread the load of long-stay care more generally, and to avoid the revival of the old chronic wards in a new guise, our general hospitals should be constructed and equipped so that every ward carries an annexe for a 20% quota of long-stay patients—say 4 in each 28- or 30-bed ward. In most general hospitals at least 40% of the admissions are aged sixty or over, and many of them must fall by the wayside in terminal illness or chronic incapacity, becoming hospital long-stay patients. Although prolonged rehabilitation of old people is not feasible in general wards, it should not be difficult to arrange the systematic routine necessary for the care of a small proportion of these chronic invalids. The geriatric unit with its much larger ratio of long-stay beds ($3^1/_2$ to 1) should be able to ensure that the 20% quota is never exceeded, and relieved of the need to accept so many long-stay patients from general hospitals, could concentrate better on its primary rôle in the active beds of reducing helpless incapacity among old people to a minimum.

The architects for the new wing are Smyth and Cowser, FF.R.I.B.A., 31, College Gardens, Belfast.

MOUNTAINEERS AND MEDICINE

P J HORNIBLOW
M.B Lond.

LAST summer, the Army Mountaineering Association organised an expedition in conjunction with the Pakistan Army, to climb and explore a remote area in north-west Kashmir called Baltistan. The expedition reached the mountains on June 20 and returned to Rawalpindi on Aug. 20. As an Army reservist, I joined it from the Persian Gulf where I had been working for three years.

There were twelve British members of the expedition, and before leaving England three of them had asked their family practitioners for medical advice. It seems likely that doctors will be asked more often for such help, for the so-called "golden decade" of mountaineering is over. Since the second world war, Everest, Kanchenjunga, K2, Lhotse, Annapurna, Makalu—the list is long and impressive—have been climbed, and there are few peaks left to attract the attention of a big expedition with all its accompanying facilities. A new epoch is beginning, of small privately financed parties, whose targets are the mountains between 20,000 and 25,000 feet in the Himalayas and the Andes. Often they are without a doctor, and they are limited in the supplies they can afford.

This is a brief review of some of the circumstances and problems which are met with in remote, mountainous areas, and which we encountered last year in the Karakoram Himalaya

BEFORE LEAVING

A number of points need attention

Teeth

A complete dental examination is important, to exclude caries and to inspect all restorations This includes a full mouth X-ray

Defective conservation seemed to be the cause of toothache in two of last year's party, once they had climbed above 17,000 feet The pain diminished or disappeared at lower altitudes It may have been due to a pulpitis, associated with insufficient insulation of the cavity, for cold air striking on metal restorations with inadequate cement linings causes pain by direct stimulation of nerve-endings in the pulp and dentine Mouth breathing is inevitable at high altitudes because of the relative anoxia, and so the incisor and canine teeth are especially exposed to the cold air, and it was from these teeth that the two men suffered pain

Any carious teeth that are to be restored should have a zinc-oxide and oil-of-cloves lining rather than cement, because the obtundent effect of oil of cloves reduces the chance of pain due to low atmospheric temperatures

Ears

Wax should be removed, for it can cause deafness and pain once a climber is exposed to the pressure changes between a base camp at about 10,000 feet and a summit of 20,000 feet or more The leader of our expedition complained of these symptoms after our first major climb, and examination showed large quantities of wax in both ears As we had no ear syringe, cleaning his ears was a tedious business It required innumerable washouts with a 5 c cm syringe, the largest in our equipment

Throat

The problem of " high altitude throat " is well known It may occur at any height above 14,000 feet, and seems to be largely due to mouth breathing in the cold dry air But apart from this " traumatic " cause, secondary infection is an important factor Three members of our party were affected at heights above 16,000 feet, and all had histories of sore throats on several previous occasions A prospective climber with such a history should have a throat-swab taken, and if culture shows pathogenic organisms these must be treated with a suitable antibiotic Tonsillectomy may be necessary before a man is considered fit to join a party planning to climb a high peak

Feet

Facilities for washing are often limited, which encourages tinea pedis The two members of our party who suffered from this complaint had suffered from it previously but it had since been quiescent, in one case for several years Any fungus infection should be thoroughly treated before the climber leaves home

Chest

Thorough clinical examination and an exercise-tolerance test, perhaps augmented by electrocardiography in some cases, will exclude hypertension, unsuspected cardiac defects, and gross respiratory disease It is unlikely that such lesions will be found in a mountaineer, for the very nature of his pastime will soon bring them to light But a chest X-ray is important to exclude early pulmonary tuberculosis, or mild bronchiectasis Past expeditions have shown that people become more susceptible to lobar pneumonia at high altitudes, where it may prove rapidly fatal despite the most energetic measures, so it is important to exclude predisposing causes Fortunately, we had no such cases

Inoculations

Whatever the health requirements of the country to be visited, typhoid-antityphoid and cholera protection should be given

ADVICE FOR THE EXPEDITION

Gastroenteritis

Few visitors to the Indian subcontinent avoid this hazard, usually succumbing within a week of arrival, but it sometimes persists away from inhabited areas It is often non-specific, and has been attributed to the chemical constituents of the water or to the reaction of normal paracolon organisms to a changed environment We were all inconvenienced to a greater or lesser extent For the 3 severe cases forty-eight hours' rest with a fluid regime of half-strength glucose-saline solution proved effective Antibiotics were not used

Heat Effects

An expedition usually involves an approach march of anything up to 100 miles from the last point of civilisation It is easy to forget that in a subtropical zone this can cause salt deficiency In the summer the Himalayan valleys are hot, and this may induce heat-exhaustion in a person carrying a load for some 15 miles a day, unless he adds salt to his food and pays attention to his fluid intake Salt is a precious commodity in the mountains, and on one occasion, through an oversight in the distribution of stores, we had to barter 100 cigarettes for half a pound of rock salt

In our party, it was usually difficult to differentiate between salt deficiency and muscular fatigue, but there was little doubt about one case

It happened at the end of the third day's march, and was probably precipitated by the man immersing himself in a hot sulphur spring, whereas the rest of the party contented themselves with soaking only their arms and legs That evening, he complained of nausea, giddiness, headache, and myalgia He was treated with saline drinks, some of which he vomited during the night, and aspirin, and next morning he felt fully recovered save for slight weakness Like all the others, he had flown from England, and this method of transport precludes any chance of heat acclimatisation

Feet

Blistered feet were a great trial in the early stages of the expedition A climber must carry plenty of adhesive dressings, and an absorbent powder is of great help

Sunburn

Once above the snow-line sunburn becomes a serious problem As the density of the atmosphere decreases, the climber is exposed to increasing ultraviolet irradiation, both from the sun's direct rays and from those reflected from the snow In addition, he is afflicted by almost continuous winds The supraorbital crests, maxillæ, lips, pinnæ, and nose are the vulnerable points A beard and untrimmed hair afford good protection elsewhere on the head and neck We all applied various proprietary creams lavishly, but sometimes they did not prevent total desquamation of the areas mentioned Sunburn remained a major source of discomfort at high altitude Eventually we found that a face-veil made of lint and wired to the lower edge of our snow goggles provided real protection

" High Altitude Throat "

Often these throats improve with acclimatisation, but in the 3 severe cases met with on the expedition a three-day course of a long-acting soluble sulphonamide gave considerable relief

Snow-blindness

Snow-blindness can be prevented by always wearing snow goggles during daylight, even when it is cloudy Despite this precaution, we still had several cases of conjunctival inflammation with pain and watering of the eyes Personal comfort becomes of such paramount importance at high altitude that, if morale is not to suffer, I believe the use of an anæsthetic ointment, such as 2% 'Butyn', is justified in severe cases In the absence of medical supervision, the climber must be warned that this can aggravate the damage unless he rests in a dark tent with his eyes covered until the condition subsides

Superficial Infection

As the weeks passed, we noted an increasing tendency for small cuts and abrasions to become infected, however quickly sterile dressings were applied Frank pus persisted, despite the use of antiseptic lotions and (later) topical antibiotic applications One climber was incapacitated for four weeks by infected blisters on his feet, and his morale suffered as he passed days in idleness at base camps Our diet appeared to be adequate, being based on Army "compo" rations and twenty-four-hour one-man packs, augmented by occasional apricots, eggs, chickens, and attar from the valley Finally, however, he was given 300 mg of ascorbic acid daily There was a dramatic response within forty-eight hours, and ten days later he ascended a mountain of more than 23,000 feet after a 25-mile approach march His remarkable improvement suggests that the bodily requirements of vitamin C are greatly increased in such a hostile environment

ON THE RETURN

When he gets home, the climber should submit stools for examination Bacillary dysentery, amœbiasis, and ascariasis are rife in the Himalayan foothills, and it is unlikely that all the members of an expedition will return unscathed

My thanks are due to Dr J Guthrie, chief medical officer, Kuwait Oil Company, Ltd, for his critical advice and help

HEALTH SERVICE ESTIMATES

THE estimated gross total cost of the National Health Service in England, Wales and Scotland in 1960–61 is £746,013,750, compared with £718,002,260 in 1959–60—an increase of £28,011,490[1] Appropriations-in-aid are estimated at £162,508,415, compared with £155,260,605 in 1959–60, and thus the net cost is set at £583,505,335, compared with £562,741,655—an increase of £20,763,680 The cost of the hospital, specialist, and ancillary services is estimated at £502,166,540, compared with £482,892,170 Under this heading advances to boards' capital accounts are estimated at £28,550,000 (an increase of £4,350,000 over the total in 1959–60) and to boards' revenue accounts at £458,537,000 (an increase of £15,336,855) The cost of the general medical, dental, pharmaceutical, and supplementary ophthalmic services is estimated at £216,194,060, compared with £208,514,895 in 1959–60 Under this heading the estimated cost of general medical services is increased over that in 1959–60 by £3,417,000 to £78,067,000, that of the pharmaceutical services by £1,287,000 to £74,622,000, and that of the general dental services by £2,599,000 to £47,400,000

The Wider World

ISRAEL AND HER HEALTH SERVICES

1948-1958

WHAT happens to the preventive and the treatment services in a "managed" country after it acquires independence? If all that has occurred is a change of government and if the services previously provided were well grounded, widely distributed, popular, and efficient, then, as has happened in Sudan[1] and in Ghana,[2] there is likely to be unspectacular advance on the lines already laid down Where independence has followed destructive war and been succeeded by enormous changes in population, what then? Might we expect brand-new health services, modelled on, or improving on, the best in the world? Or makeshift improvisation till financial and organisational winds blow warm?

Since Israel declared her independence in May, 1948, she has been under intense economic and financial strain, with almost continuous military mobilisation, hostile neighbours, and mass immigration What have been the reactions of her medical services to these years of anxiety and uncertainty? We reviewed[3] an earlier report describing their evolution from 1948 to 1952, and a new one[4] brings the record nearly up to date

THE LAND OF ISRAEL

This small State occupies 8000 square miles, of which about a fifth (a million acres) is devoted to agriculture. More than a third of the population is housed in 705 villages

To provide food for the rapidly increasing population, one of the country's main aims has been to irrigate desert tracts Soil conservation by afforestation, intensive mechanised agriculture, and the development of new water sources have been active preoccupations In the decade after the establishment of the State, agricultural output increased threefold and industrial production doubled. Citrus fruits are the most important export. Industry has been developed, the main factory and workshop employment being in diamond finishing, small crafts and industries, metallurgical, chemical, and pharmaceutical manufactures, and textiles New building for agriculture, industry, and public life has transformed the land, together with half a million living-rooms in 150,000 permanent new dwellings

THE PEOPLE

In 1958 the population just reached 2 million, of whom a tenth are Arabs During the preceding ten years, over 900,000 Jewish immigrants from almost all parts of the world had been admitted and somehow absorbed into the economic, social, and cultural life A country in which nearly half the population are newcomers faces problems unique in the modern world A quarter of the Jewish population is middle-aged or older, 40% are between 15 and 45 years of age, and a fifth are of school age.

A quarter of the Jewish population and three-quarters of the Arab citizens live in the countryside. Of the whole employed population 15% are engaged in agriculture, 10% in building, 25% in mining and manufacture, and 30% in public services of various kinds[5] The Arab section of the population living mostly in Galilee is over 200,000 strong and includes a large agricultural Druse community and 22,000 Beduin. They have lately been described[6] as "reasonably content and living well."

Two-thirds of the Jews are immigrants. They are mostly people who have suffered much strain, and the resulting tensions and psychological stresses constitute a major problem for the new State.

IMMIGRATION WAVES

International migration has a history as old as organised man. Before the 19th century, group migration was the usual pattern. The Huguenots left France at the end of the 17th century because of religious persecution. Later, French colonial policy directed Frenchmen to Canada to found the "new France." The movement of Negro slaves from Africa to the Americas had reached a figure of 14 million by 1850.

During the 19th century some 60 million people left Europe, mainly because of bad economic conditions. Most went to the Americas, Canada, and Australia. 20th-century migration before the 1939 war was less massive and more selective.

Argentina and Brazil welcomed Catholics and did not want Japanese or Asiatics. Pre-war Italy was anxious to prevent migration elsewhere than to her new colonies in Cyrenaica, Tripolitania, Somaliland, and Ethiopia. The United States introduced a "quota" immigration policy to restrict total numbers, to limit ethnic groups to fixed proportions, and to exclude Asiatics, Chinese, and Japanese.

The growth of population in Israel since 1948 has been largely by sudden streams of immigrants, drawn from countries in Europe, Asia, and Africa where hostility dictated a systematic exodus of all or of large sections of the Jewish communities. Their need was for asylum and security. This variety of immigration differs qualitatively from the more familiar voluntary type undertaken for economic reasons, and the difference accounts for Israel's immigrants having more whole families, widows and children, and sick and disabled.

Earlier, waves of immigrants had come from Russia before the first world war, and from Poland in 1924–36. Refugees from Nazi Germany, Austria, Czechoslovakia, and the Baltic States came between 1933 and 1939.

After 1948, some 300,000 survivors of the Jewish communities from Germany, Poland, Yugoslavia, Bulgaria, and Rumania sped to Israel. Since 1950 masses of Oriental Jews from Morocco, Tunisia, Yemen, and Egypt, and the whole community of 120,000 from Iraq, have sought shelter in the new State. Smaller groups came from India—including "the black Jews of Cochin" in Southern India, as *The Times* called them.[7] A group from China, who originally went there from Russia at the turn of the century, have recently arrived.

These population groups, with differing national origins and different upbringing and ways of thought and behaviour, tend in many respects to remain socially loculated. There has been almost no intermarriage between any of the Jewish, Moslem Arab, non-Arab Moslem, Arab Christian, non-Arab Christian, Druse, and other groups of Israel's population.

ABSORPTION OF THE IMMIGRANT

Their unhappy experiences in the country of origin, their housing and economic difficulties on arrival, problems of religion, language, food customs, and new employment—all these combine to create difficulties in the settlement of new immigrants.

After a long study of one group from Holland, Bachi[8] concluded that it takes three years to achieve satisfactory adjustment and ten years to sink deep roots. A knowledge of Hebrew was an important prerequisite to success. Frequent contact with intimate fellow-immigrant old friends from Europe improves the chances of successful settlement. On the other hand, an immigrant in this group did not seem to adjust more easily if he followed the same occupation in Israel as in Holland. In a similar study among a Yemenite Jewish group, Bachi reported that in the process of assimilation, social characteristics change more rapidly than demographic ones. These Yemenites, who had settled in Jerusalem, tended to relinquish their traditional ways, and to acquire the social habits of Israelis of Western origin, before showing change in their fertility pattern.

The process of adjustment involves a physical transition from one society to another, generating personal frustrations and social problems. The immigrant has to contend with the different outlook of the indigenous residents and —even more bewildering—with the gap between his slow adaptation to the new country and its ways and the rapid acceptance and assimilation of his growing young children.

Essentially the cultural assimilation of an immigrant is the process of becoming absorbed into the host community, accepted as a wholehearted citizen of the new country. Success in this depends on personal make-up, on enthusiasm for the new country, on the attitude of the receiving Government and its people, on language problems, colour difficulties, competition for work, homes and spouses, and on other less tangible factors.

Failure to assimilate is manifest as a separateness of the individual or group within the host community, retaining the accustomed living patterns, language, group newspapers, and schools, and marrying within the ethnic groups. This failure, in a country which has welcomed the immigrant, may derive from or may lead to psychological disturbance.

IMMIGRATION AND THE PUBLIC HEALTH

The mass waves of immigration during 1949–51 were characterised by a predominance of young children and old people. Half these migrants came from "backward" countries with primitive sanitary customs and high sickness-rates. During this period the Israel infant-mortality rate rose to 52 deaths per 1000 live births. (It had been 29 in 1947 and was down to 33 by 1957.) There was a rise too in mortality from tuberculosis, diphtheria, and typhoid. A severe outbreak of 5800 cases of poliomyelitis in 1950 killed 650 in one year and left 2000 cripples for whom special orthopædic and educational arrangements have been developed. Immigrants from North Africa and Arabia included sufferers from malaria, leprosy, trachoma, and typhus. During 1952 immigrants from Iraq, Egypt, Morocco, and the Yemen included 25,000 carriers of bilharzia. The Indian contingent from Cochin brought filariasis with them. Infective hepatitis occurs mainly among immigrants from Europe.

A high incidence of mental sickness has been a feature of all the large groups of immigrants. Housing difficulties and food shortages accentuated high rates of intestinal infection and worm infestation.

In 1957 among 30,000 immigrants from Poland there were 106 cases of pulmonary tuberculosis, 120 amputees, 70 diabetics, 25 blind, and 8 mental defectives. In the same year among 13,000 Jewish immigrants from Egypt there were 110 cases of heart-disease, 80 diabetics, 95 blind persons, 25 cases of pulmonary tuberculosis, and 30 mental defectives

EPIDEMIOLOGICAL SITUATION

With expansion of health services, the ten years have seen a reduction in preventable infectious disease and in mortality

There have been no cases of *plague* since 1948

In 1952 there were 968 cases of *typhoid* An attempt was made to inoculate the whole population with T.A.B vaccine but only a third were reached In 1957 there were 333 cases

Amœbic dysentery is widespread 9000 registered cases are known and 1200 new cases a year are diagnosed

Gastroenteritis is one of the leading causes of infant mortality It occurs mainly among the children of Afro-Asian immigrants and in the summer it fills the children's beds in hospitals Many children have several attacks No constant bacteriological cause has been identified, though Coxsackie and Echo viruses were responsible for some cases in 1958 A low standard of personal hygiene, even in areas of good sanitation, is held to account for the high incidence of salmonella and shigella (Sonne during June, Flexner in October) infections The paucity of domestic refrigerators and the orthodox Jewish proscription of cooking on the sabbath are contributory factors to the prevalence of food poisoning 41% of the reported outbreaks in 1958 were due to staphylococcus enterotoxin

There has been a steady drop in *poliomyelitis* since the peak incidence in 1950 Most young children have received Salk vaccine injections

Whooping-cough produces 20,000 cases a year

Streptococcal infections are endemic and 900 cases of *acute nephritis* and 1200 of *rheumatic fever* are seen annually The incidence of rheumatic heart-disease is higher in Israel than in European countries

Murine typhus has fallen since the practice of regularly spraying rat runs with D D T was adopted

"*West Nile fever*" is a recently identified, late-summer short-term febrile illness of virus ætiology specific to Israel and believed to be transmitted by *Culex molestus* mosquitoes

Rabies still occurs and 18,000 wild dogs are destroyed annually in the frontier districts

Infective hepatitis produces over a thousand cases annually, mostly in December and January and in communal villages where streptococcal tonsillitis infections are also epidemic

Malaria, once a scourge, has been well controlled A few *Plasmodium vivax* infections occur in villages and occasional cases of *P malariæ* infection have followed blood-transfusion

Schistosomiasis outbreaks have followed bathing in irrigation water A recent survey by the department of parasitology of the Hebrew University of Jerusalem disclosed 80 breeding-places of *Bullinus truncatus* Multiplication of these snails was inhibited by increasing the salinity of the water, but this could not be done in ponds used for artificial breeding of freshwater fish—an important food industry in Israel

Tuberculosis incidence has fallen considerably since the abnormally high rates of 1948–51 The development of chest-clinic services, mass radiography surveys, B C G vaccination, and free hospital treatment have reduced new cases to 5 per 10,000 Jews and 4 per 10,000 Arabs Among the seminomadic Beduin in the Beersheba region the incidence was found to be higher than in the village and urban Arab population

THE HEALTH SERVICES

Between 1920 and 1948, when Palestine was governed by Britain under a League of Nations mandate, the Jewish community developed and organised its own health and hospital services These were coordinated by the health department of the National Committee of the Jewish Community in Palestine and were in a position to provide the nucleus of the new Ministry of Health when the State of Israel was created The Ministry is the supreme authority in matters relating to health and is also the licensing body for the medical and allied professions The Minister has cabinet rank and his department is managed by a medical director-general and four assistant directors, two of whom are lay administrators Three-quarters of the Ministry's budget is for hospital services The Ministry supervises and attempts to coordinate the treatment and preventive services provided by its own departments and those belonging to and financed by local authorities and private voluntary bodies The contribution of the latter is so extensive, important, and independent that it merits special description

The largest provider of private medical services in the country is the *Kupat Holim*—the sick fund of the General Federation of Jewish Labour Founded in 1912 with 150 members as a voluntary comprehensive health-insurance scheme, it has grown steadily till it now provides medical services for 66% of the Jewish and 16% of the non-Jewish population, the insured and their dependants The organisation spends 80 million Israeli pounds a year to provide complete medical and dental treatment for $1^1/_4$ million of the population through 927 clinics, each equipped with laboratories, X-ray department, and physiotherapy service, 15 general and special hospitals with 2391 beds, 15 convalescent homes with 1881 beds, and 196 mother-and-child welfare centres In addition, this organisation supervises industrial health in factories, workplaces, and new village settlements, and provides public-health education, issuing its own monthly health magazine *Kupat Holim* employs 1596 medically and dentally qualified staff, 2500 nurses, and 4500 ancillaries Its funds are derived from a 3% insurance levy on its members' wages with a further 2 7% of the wages contributed by employers and a Government grant of 8% of the total budget

Malben is a private organisation founded in 1949 to provide for aged sick and physically handicapped immigrants It maintains homes for 4500 aged persons without relatives, 4 hospitals with 674 beds for chronic disease, a hospital for chest cases, and outpatient and dental clinics, and it lends money to disabled immigrants to enable them to set up small businesses

The *Hadassah Organisation* started in 1913 with private funds collected mainly in America to provide a district medical service in Jerusalem. In 1918 it built hospitals in Jerusalem, Jaffa, Haifa, Safed, and Tiberias In 1921 it opened the first maternity and child-health centre in the old city of Jerusalem. In 1939 it provided a magnificent medical centre at Mount Scopus comprising a teaching hospital and university research laboratories Many British Army doctors stationed in Palestine during the second world war got instruction in parasitology and malaria control in these attractive buildings In 1948 Hadassah's preventive medical services were transferred to the new Ministry of Health, except those in the Jerusalem locality which were retained for training of medical and nursing students

Hadassah recently started a pilot project near Jerusalem to provide combined preventive, diagnostic, and curative health care for whole families The intention is to study the possibility of providing for a local community a mixture of our Peckham Pioneer Health Centre, family (home and surgery) general practice, and preventive health-clinic services, with undergraduate medical teaching, all operating from under one roof and one medical management.

Reviewing the Israeli medical scene after a visit last November, Dr George Silver,[9] of the Montefiore Hospital in New York, accepts the accomplishments as indicating an advance from 19th-century problems of sanitary reform to 20th-century problems of improved organisation in medical practice Drawing attention to the "extremely high utilisation of medical service by the patients", he gives as one possible explanation the fact that impersonal care leads the patient to make repeated demands, seeking satisfaction In large areas of Israel continuity of care through a family doctor is lacking

---

[9] Silver, G A Report of a visit to Israel, 1959 Privately circulated

The varying ownership of the hospitals makes their coordination difficult A country with a population hardly bigger than that of one of our hospital regions has an opportunity to demonstrate how to achieve unity without uniformity Integration is a necessity, but it would be well to avoid the situation of one large municipal authority in England some thirty years ago, where at lunch-time a senior administrator could proudly tell his visitor that "at this moment 40,000 patients are eating green peas" Israel's Minister of Health remarks cautiously on the "trend now to transfer various health services to the Ministry at a rate which is rather too fast for us"[4]

Public Health

Strontium 90 in Milk and Agricultural Materials

A NEW Agricultural Research Council report[1] is the second of a series dealing with the contamination of human diet in the United Kingdom with strontium 90 (^{90}Sr) from worldwide fallout after test explosions of atomic and nuclear weapons It records the levels in milk, the major source of ^{90}Sr in diet in this country, during the first half of 1959 The mean content of ^{90}Sr in the total diet cannot be assessed at six-monthly intervals because many of the foods other than milk which contribute ^{90}Sr to the diet are harvested at only one time of the year A report on the levels in total diet during the whole of 1959 will be published in some months' time

For the 12 months ending June, 1959, the average level of ^{90}Sr in milk was 9 6 micromicrocuries (µµC) per g of calcium —i e , an increase of about 40% over the 12 months' average for the period ending in December, 1958 For the ten zones into which the United Kingdom is divided, the 12-month mean values at the end of June, 1959, range from 7 8 to 14 9 µµC of ^{90}Sr per g of calcium, the higher values were for the wetter parts of the country

Results are given for a number of "special areas" which are being investigated to ascertain the highest levels of ^{90}Sr in milk which varying local conditions can produce The highest mean value for the 12 months ending June, 1959, was 32 µµC per g of calcium from a small area in mid-Wales This was nearly 20% higher than the mean value for 1958 in the same county

The proportion of strontium to calcium which is transferred from diet to human bone is only about one-quarter of the proportion of strontium to calcium in the diet Thus the proportion of ^{90}Sr to calcium in new bone formed during the 12 months ending June, 1959, when the average level in milk was 9 6 µµC per g of calcium, would be approximately 2 5 µµC per g of calcium in children who live on milk alone In no large area of the country would this value be exceeded by more than about 50% but in the special area which gave the highest 12-month mean value in milk the corresponding value, assuming that only local cows' milk was taken, would be 8 µµC

In 1956 the Medical Research Council expressed the view that the level of ^{90}Sr in the bones of the general population should not exceed 100 µµC per g of calcium and that if the level showed signs of rising greatly beyond one-tenth of this value—i e , 10 µµC—it would be desirable to give immediate consideration to the situation The Medical Research Council is at present undertaking a comprehensive assessment of the significance of all evidence now available on the exposure of man to all sources of radiation, including the contamination of diet with fallout

The present results support the conclusion that the level of strontium in milk is determined mainly by the quantity of fallout deposited in the immediate past and not by the cumulative total in the soil Therefore if weapon trials are not resumed and the rate of fallout consequently decreases, no further increase in the levels of ^{90}Sr in milk is expected even though ^{90}Sr will continue to accumulate in the soil The increase in the levels in milk during the period covered by this report is attributed to the high rate of fallout between November, 1958, and May, 1959, resulting from atomic weapon trials in northern latitudes in the autumn of 1958 The 12-month mean value observed in milk for the period ending June, 1959, may be regarded as the best estimate now available of the highest average level in milk likely to result from ^{90}Sr so far released Such information as is available for samples collected after June, 1959, shows that values have in fact decreased

The recent atomic tests in the Sahara, involving explosions in the kiloton range, are not expected to have any significant effect on the level of worldwide fallout

Statistics for England and Wales

The Medical Tables of the Registrar General's Statistical Review for 1958[1] give detailed statistics of deaths from all causes and notifications of infectious diseases by age, sex, area of residence, and time of year

The death-rate was 11 7 per 1000 population—0 2 higher than the rate for 1957, the rate of 0 88 for children aged 1–4 was the lowest ever recorded for England and Wales The stillbirth-rate was 22 per 1000 total births The infant-mortality rate of 23 per 1000 live births equalled the record low rate of 1957 The perinatal mortality-rate was 35 per 1000 total live and still births

Deaths from cancer of the lung numbered 19,820 (17,040 male and 2780 female)—an increase of 701 over the 1957 figure These deaths accounted for a third of the male and for 6% of the female deaths from cancer For males, the death-rate from cancer of this site per 100,000 population has increased from 65 in 1954 to 78 in 1958 (and for females from 10 to 12) The death-rate for cancer of the lung is highest in the age-groups 65–74 and 75 and over, the rate for those age-groups has increased for men from 303 and 187 per 100,000 population in 1954 to 392 and 274 in 1958

The death-rate from tuberculosis was 15 per 100,000 population for males and 5 4 per 100,000 population for females

Population Forecasts

The Registrar General's quarterly return for the December quarter, 1959,[2] includes population forecasts On certain assumptions, one of which is that annual births will average 730,000 in the first five years, thereafter rising gradually to 790,000 in 1997 and later years, the total population will increase from 45,504,000 (as at June 30, 1959) to 46,468,000 in 1964, 49,230,000 in 1979, and 52,384,000 in 1999 The projections show that the excess of 1,500,000 females in 1959 will decrease gradually until in 1999 there will be only 512,000 more females than males The proportion of the population of pensionable age (males 65 and over, females 60 and over), which is at present 14 7%, will increase to 17 6% in 1979 and 17 9% in 1989 but will decline slightly to 16 7% in 1999, if assumptions are borne out by events

In England Now

A Running Commentary by Peripatetic Correspondents

ONE of the impressions gained on our visit to the United States is that mechanisation has an important place in medicine. Heart-lung machines and artificial kidneys abound, but the most ingenious machine, to our mind, is the coffee-cum-milk-cum-soft-drink dispenser This is no less ingenious than the most complicated cardiac pump The latter has only to pump a few pints of human blood, but have you ever considered the complexity of a coffee dispenser? Do you know how much coffee must be added to how much milk—at just the right temperature—to produce just the correct amount of beverage? Have you considered how the machine distinguishes between "hot, black, and brown sugar" and "hot, cream, and white sugar"? Have you ever wondered how the cup always arrives first, then the coffee, then the cream, and lastly the sugar, and always in that order? Consider for a moment the degree of organisation required, and you will realise that the artificial kidney is but a toy compared with even the most primitive coffee-dispenser

This is not all. Our soft-drink dispenser can distinguish between different coins, and can deliver the correct change It will even distinguish between American and English coins, and refuses to function if offered a sulpha tablet. The machines are in fact very choosy about how they do function, and one day last week ours refused to work even when supplied with genuine nickels Worse still, it refused to return the coins We found, however, that a dime would work, but still we could get no change. The machine obviously needed a lesson. We decided to cystoscope and catheterise it.

With this particular patient the operator has to lie on his back, and direct the cystoscope almost vertically towards the delivery pipes to obtain successful cannulation. We had several blind trial runs, and eventually settled upon orange squash for our first attempt. It was quite easy, all we had to do was to introduce the ureteric catheter into the pipe, insert a dime, pull the lever, and push home the catheter We obtained 1½ gallons of orange squash and 50 nickels change at our first attempt. At a nickel per cup, and 50 cups to the gallon, that came to—to—well, quite a lot of money We planned to cystoscope all the coffee machines

And then the news reached the chief. He insisted on a demonstration. Would he want a cut in the profits, we wondered. We showed him how to obtain orange juice, then milk. Finally he insisted on trying himself. With many a contortion he inserted the cystoscope, held the catheters ready "Ready," he said, and we dropped the nickel into the slot. To our horror we noticed too late that the dial read "Hot coffee, black" The chief is back at work now, the cystoscopes are kept under lock and key, and we leave for England soon.

* * *

In my innocence, I had always imagined that the production of an H.M. Circular was a process of almost elephantine gestation. When, let us imagine, some glaring anomaly in the London weighting of pay-scales for Apprentice Hospital Piggery Attendants had been obvious to all those immediately interested for a year or two, rumours of unrest would penetrate the cloistered calm of Savile Row The Whitley machinery would be cranked up and groan into action, management and staff sides would, pavane-like, advance and retire. Interested bodies would be consulted at all conceivable levels, evidence would be taken, deputations received Ever more bulging files would be passed by perspiring messengers from room to room, floor to floor, building to building, from Ministry to Treasury Then they would lower the sights and start again Eventually, perhaps after the stimulus of a question in the House, a draft circular would be produced, circulated, modified, amended, and re-drafted. The plainest of Plain Words would be carefully assembled, perhaps (or would this be too much to hope for?) Sir Ernest Gowers himself would be brought in. Astrologers would be consulted to ensure that the number of the circular was auspicious—and then, off to the printers and out it goes

Imagine, then, my disillusion on reading in the minutes of a Ministry meeting (I mustn't be more precise for they were headed "confidential"), the bald statement "A circular *will issue* shortly" My precious dream was shattered. Circulars are not produced, they reproduce themselves It is simply a matter of parthenogenesis.

* * *

The last bastion of culture down our way has finally crumbled My friend who used to read books and think thoughts has finally got himself a telly and now they can only un-glue him from the screen long enough to feed him. He's still a bit weak on idiom though "I will get myself a passage on the stage-coach to Dodge City" should more properly be "I'll hitch me a ride on the stage to Dodge" But he's learning He used to answer the phone with "This is Mr Robert Blink, consulting ophthalmic surgeon, South Western Region, area 6" Now it's just "yup"

* * *

Today I went to my bank and came out with my usual feeling of spiritual uplift. What, no overdraft? Well, as a matter of fact The real reason for the uplift goes back thirty years

I was sixteen, and a boarder at a public school. My father, in India, was getting tired of paying fees He suggested that it was time for me to earn some money So it was arranged that I took the entrance examination to the Central Bank. I passed with flying colours, attended the headmaster's farewell tea, signed his book, and left school. My medical aunt was acting as my guardian in England. I went to stay with her for the Christmas holidays I called to see the local staff superintendent of the Central Bank. He said he was delighted to see me. He added that my salary would be £60—per annum, of course. I went back and told my aunt. She was never one for a roundabout approach to things "This", she said, "is ridiculous do you want to go into a bank?" I said No, but it was a question of money "Have you ever thought of doing medicine?" she asked. I hadn't, but I did, and rather liked the thought. But what to do for money? "Never mind about that", said my aunt "I'll write to your father" Bless her, she offered to keep me, if he would pay the fees He agreed. I returned to school to await the next autumn term at the university I went to the headmaster's tea a second time, which was allowed, but did not again sign the book. "One of you has been enough," said the headmaster

Eventually I qualified and after twelve months I had earned enough to need a bank. What more natural than that I should choose the Central? And so, every time I cash a cheque, I study the cashier with interest. "There", I say to myself, "but for the Grace of God—not forgetting my aunt—would I be standing"

As a matter of fact I enjoy having an overdraft.

MAL DE MÈRE

So you feel that your Johnny is delicate,
He is rather off-colour again?
Well, perhaps you would tell me his symptoms—
Of what does the patient complain?

Yes, I know he's behind in his schooling,
I'm aware that you've nursed him in bed—
But pray what, Mrs Smith, was the *reason*?
Or did I miss something you said?

It's a curious fact about Johnny
That whenever he comes here alone
He's a perfectly healthy young rascal
And we have a quiet chat on our own,

But whenever his mother comes with him
He's riddled with morbid disease
He looks ill—he feels ill—he *is* ill—
Can someone explain to me, please?

Letters to the Editor

THE PERSONAL DOCTOR

SIR,—In Dr Fox's thoughtful article last week he says general practice is dead or dying in this country that "Except in isolated places, the general practitioner is already extinct "[1]

The American Academy of General Practice, our own College of General Practitioners, the College of General Practice of Canada, the Australian College of General Practitioners, and similar organisations in the Netherlands, Germany, and elsewhere are all firmly established and working hard for this important branch of medicine They are all based on the concept of a "general practitioner" and are proud of it Is this really the time to embark on a new international nomenclature and change his name to "personal doctor"?

There is an important difference, which is not always appreciated, between which we know as "general" practice and the purely hypothetical "comprehensive" practice of the whole of medicine by one man Even in the time of Hippocrates good family doctors did not try to do everything—"I will not use the knife, not even on sufferers from stone, but will withdraw in favour of such men as are engaged in this work" Nowadays, there are many hundred modern techniques for diagnosis and treatment which are beyond the scope of any single practitioner, wherever he may work But the fact that he cannot do complicated biochemical or pathological investigations, cardiac catheterisation, renal biopsy, major surgery, or radiotherapy does not lessen in any way the need for his training and outlook to be *general*, so that he may provide or arrange the correct care for all his patients whatever may be wrong with them

If his professional interests are broad, and he is versatile and widely informed, the term general practitioner is not out of place, if they are not, he will be of little use as a medical adviser at all The reputation of quacks depends on confidence established in personalities who have little general medical knowledge The terms "general practice" and "general practitioners" still seem good to many of us, especially as they have been identified for so long with family practice and family doctors

Our worth has been recognised for thousands of years as being largely personal doctoring Dr Fox outlines skilfully the better conditions which most of us think we need to help us do this job better, and points out how very important personal care still is today We must all agree with much that he says, but to change our title at this stage from G P S to P D S would, I think, lead to confusion and be a mistake

I must take him up on one other debatable point Under the heading of General-practitioner Beds he says "Outside the hospital services the personal doctor is in charge inside them he is an agent for the specialist" Like others who have suggested this before, he gives no good reason why the care of a patient with a not very serious illness (such as cystitis, mild infective hepatitis, or early congestive heart-failure) should not remain the responsibility of his family doctor, when he has been admitted to a general-practitioner bed in a hospital merely because there is no-one to look after him at home Where there are general-practitioner beds, general practitioners must be in charge of them, with the same right to seek consultant advice and help as for other patients treated in bed in their homes

London S W 1 **JOHN H HUNT**

PSYCHIATRIC DAY HOSPITALS

SIR,—The introduction of day hospitals has been one of the most important changes in psychiatric care during the past 12 years Patients able to remain with their families at night attend during the day for various forms of physical and psychological treatment with the social advantages to the patient and economic ones to the health services which are already well-known [1–3] The first day hospital in this country opened in 1948 and there are now at least 40, plus 5 mental aftercare homes[4] New ones are opening all the time and the movement will undoubtedly play an important part in future mental health services[5] Patients in day hospitals become, by virtue of the social criteria and quality of illness that led to their selection, a special group, and their comparison with inpatients—even, for example, the very thorough attempt of Craft[6]—is of slightly doubtful validity Thus although it is believed that the prognosis, duration, cost, &c, of treatment in some day hospitals compare favourably with inpatient care we cannot yet be quite certain of it, and one can easily imagine an inactive day hospital becoming a long-term refuge for a small number of inadequate personalities without doing anyone very much good Nor is there, as yet, any estimate of the proportion of the psychiatric patient population that might be treated on a day basis, though in the U S S R provision is apparently made for 5–10% of "nerve and psychic patients"[7] The call of the pioneer Dr Joshua Bierer[8] for 12–16 more day hospitals in London has stimulated us to examine the cases seen in the Maudsley Hospital emergency clinic with a view to determining what proportion of these patients might be managed in this way

This emergency clinic was started in 1953 to assist in the diagnosis and disposal of psychiatric patients thought to be in need of immediate help Most of these are referred by family doctors, usually with a view to admission, although some arrive without a letter asking to be seen, and a few are sent by other hospitals or social agencies Self-referrals are returned to their G P S, except where there is evident urgency, and are not accounted for below Almost all cases are from the Metropolitan area During the months of November and December, 1959, we noted the details of each patient seen in this clinic together with an assessment of whether or not day-hospital care was appropriate *if there were a day hospital with an immediate vacancy within ready access of home* This distance was put by the late Dr Arthur Harris as a half-hour's journey, and we also used his criterion of selection that the patient should be too ill to continue leading his normal life[1]

Other criteria for day-hospital care were that the patient should desire treatment, that there should be some adequate persons able to be with him at night, that he should not be so disturbed or suicidal as to be unmanageable at home, that he should not be primarily addicted to alcohol or drugs, and that he should not suffer from so severe a travel-phobia as to be unable to make the journey Certain indecisive depressives were also excluded, owing to the daily ordeal of incertitude as to whether or not they felt capable of leaving the house Careful judgment was often required, for while close home

8 Bierer, J *Lancet*, 1959, ii, 737

relationships often indicated treatment in the community, those same relationships could sometimes impose an intolerable burden upon a family where one member was mentally ill, which might well be reflected in the further deterioration of the patient, it is foolish to keep one patient out of hospital at the risk of creating several others

Our decisions were based solely on the need for treatment and did not reflect the particular admission policy of the Bethlem Royal and Maudsley Hospitals which, as is widely known, have two fairly small inpatient departments devoted to teaching and research The cases sent to our clinic may have been biased for this reason, though the fact that ours was the only service of its kind in the area makes this, perhaps, of little account

The details were as follows

Total of cases seen in November and December, excluding multiple referrals, 273

Suitable for day-hospital care 109 (*40%*), among whom women outnumbered men by 2 to 1

Unsuitable

(*a*) On the ground of severity, including several without adequate family support 55 (*20%*)

(*b*) Those insufficiently ill, for whom outpatient care was thought adequate 108 (*40%*)

Provisional diagnoses of the 109 suitable cases	
Depression	63 (*58%*)
Neurosis	25 (*23%*)
Schizophrenia	12 (*11%*)
Personality disorder	7 (*6%*)
Other	2 (*2%*)

Actual disposal of these cases	
Admitted to a day hospital	9
Admitted to a psychiatric bed	53
Under outpatient treatment	37
Awaiting outpatient appointment	10

The high proportion of women in the sample is accounted for by the preponderance of depressives, which is to be expected within a group of psychiatric emergencies The three of us saw cases in approximately equal proportions, and there was remarkable concordance between our figures, the greatest difference being that one of us (M R) placed 13% fewer cases in the " suitable " category with a correspondingly larger number in the " insufficiently ill " group This was probably an index of that sample of patients, the sex-distribution among the three samples, for example, showed greater differences

We should point out that our hospitals each have in the grounds a day hospital with some 30 places That at Maudsley was opened in 1953 and that at Bethlem in 1956 Waiting-lists at Maudsley and inaccessibility, mainly at Bethlem, made a larger referral impossible

We cannot claim that our cases are representative of all psychiatric emergencies in London (though we see little reason to believe that they are not) and still less are they representative of all cases referred for psychiatric treatment The routinely referred " cold " cases that can wait several weeks for an appointment are likely to be even more suitable for day-hospital treatment, should it come to that, than our fairly acute group, whereas many other more disturbed cases were admitted directly to observation wards and mental hospitals That our judgment was subjective within the broad criteria laid down cannot be denied, and it may well be that longer and wider experience would have given us confidence in extending the scope of would-be day-hospital referrals Psychiatrists so far have tended to think of such care as an occasional alternative to ward admission, and it is noteworthy that the consultants who run our 2 day hospitals refer more cases to them than do the others [9]

In sum, we consider that of 273 consecutive cases seen as emergencies, 2 out of 5 were suitable for day-hospital treatment, 2 were too mild, and the remaining 1 too ill Of suitable cases, half had to be admitted forthwith to a bed owing to lack of facilities or vacancies in the day hospital, and the remaining half are still under treatment as outpatients Some of these will doubtless come to admission in due course A large number of patients remain, however, for whom day care is impossible Nevertheless we conclude that a larger number of strategically placed day hospitals in the London area is called for, preferably with their own transport, although our figures do not tell us how many Such an estimate could, however, be arrived at and should, in our view, precede planning There should also be some concept of what the day hospital is setting out to do Enthusiasm, however well placed, has so far been allowed precedence over careful evaluation

We are grateful to the physicians of the joint hospitals for permission to publish this letter, which does not necessarily represent their views

GENETIC MECHANISMS IN HUMAN INTERSEXES

SIR,—Recent speculations about genetic mechanisms in man [1] [2] would be more valuable if they were consistent with known facts Most of the possibilities were considered for the chromosomal intersexes before the mechanism of meiotic non-disjunction was recognised [3] Since then the problem of chromatin-positive Turner's syndrome and of chromatin-negative Klinefelter's syndrome have been considered,[4] and a chromosomal aberration involving duplication or deficiency of feminising factors on the X chromosome could, among other possibilities, explain familial gonadal dysgenesis [5]

But speculation, particularly in detail, must be consistent with fact Pure gonadal dysgenesis may be due to a chromosomal aberration with gonosomic mosaicism, but the obvious cause is an autosomal recessive gene Reported familial cases include a sibship with one chromatin-positive and one chromatin-negative case,[6] and parental consanguinity has twice been reported in probable examples of the syndrome [7] [8] Additional evidence must be adduced in favour of a mechanism a priori less likely before it can be preferred to the simple one Similar considerations apply to speculation concerning true hermaphroditism Crossing over may occur between the X and Y chromosomes, although there is little evidence for it [9] The reports of familial cases of true hermaphroditism [10] [11] further weaken the hypothesis Some defects in Turner's syndrome are similar to those produced by autosomal genes,[12] and in the chromosomal intersexes it is most probable that multiple defects are due to disturbed genic balance Other differences may be due to hormonal effects [13] rather than direct genic effects [14] The alternative hypothesis of linked genes on the X chromosome with deletion of two or three is less likely A logical extension of this would be to expect deletion of only one such gene, but sex-linked dwarfism is unknown in man Nor does speculation [1] fit the facts concerning the presence of

chromatin-negative nuclear sex and ovarian tissue It should be remembered that the chromosomal sex was established to be XO in a patient who menstruated for several years [15] and that the polymorph morphology was of female type in one of the references cited [16]

Finally there is the problem of the sex chromatin body whose nature is still unknown. It has been reported that one but not the other X chromosome is heteropyknotic in the rat and it has been suggested that sex chromatin is of paternal origin [17] This is not so in man, for in some cases of chromatin-positive Klinefelter's syndrome [18] both X chromosomes are of maternal origin.[3] There is a very simple explanation for the presence of the sex chromatin body which has not, as far as I am aware, been previously advanced. In the intermitotic metabolic nucleus the heterochromatin of one X chromosome is apparently necessary for and engaged in the metabolic business of the cell and therefore not stainable The heterochromatin of any other X chromosomes is, however, superfluous to metabolic requirements, functionally inert at this time, and therefore stainable, usually at the nuclear membrane This hypothesis would explain the reported findings with respect to sex chromatin in subjects with normal (XX, XY) and abnormal (XO, XXY, XXX) karyotypes

GENETICS OF SCHIZOPHRENIA

SIR,—In your instructive annotation of March 26 the terminology is irritatingly inaccurate You refer to twins wrongly as "monozygous" or "dizygous" instead of monozygotic or dizygotic (Identical and fraternal are acceptable terms also) Homozygous and heterozygous are standard terms which refer to chromosomes and genes which are same or different, "monozygous" and "dizygous" have no meaning at all In twins the things which are same or different are zygotes

A slighter cause for complaint is the use of the term "sibling" for brother or sister Tradition in England, supported by such authorities as Crew, Fisher, Haldane, and Hogben, insists on the word sib A set of brothers is a sibship, not a "siblingship"

OVERSHOOTING ACTION OF PHENELZINE

SIR,—One of the impressive experiences of the psychiatrist using active physical treatments is the occasional alteration of the patient's mood from depression to hypomania following convulsive therapy This, although very undesirable, points to an effect of the treatment on the basic mechanism of affective disorder If an anti-depressant drug can be found to produce the same alteration it should probably be equally effective

In 3 patients out of 46 depressives treated with phenelzine ('Nardil') in this clinic, medication had to be discontinued because of hypomanic and manic symptoms 2 of these patients had a history of elated episodes before, but all 3 were at the start of treatment in a state of severe depression with retardation, fear, and hypochondriacal complaints, deep despondency, and self-reproach This condition had been present for a number of months, the change took place after three weeks of medication in 2 patients, after twelve days in the 3rd Restlessness, over-talkativeness, flight of ideas, distractability, cheerfulness, heightened self-confidence, and argumentative and quarrelsome demeanour were among the more prominent symptoms, and there was a tendency to dress garishly and to annoy people near the patient. After the drug was stopped, the hypomania subsided in 1 case and depression returned, in the 2nd case chlorpromazine was required to overcome the elation, the 3rd patient had to be admitted to a mental hospital because of his disturbing behaviour All 3 cases have now recovered and their mood is normal

This overshooting action of phenelzine corresponds to the generally favourable impression gained at this preliminary trial in which three-quarters of our patients improved and more than half became symptom-free at the end of five weeks' treatment A controlled investigation comparing phenelzine with other anti-depressant drugs has been started.

NORMAN W IMLAH

KEROSENE (PARAFFIN) POISONING

SIR,—While I agree with some of the ideas expressed by Dr Capel and Dr Ward Gardner (Jan 30) I feel that the danger of generalisation on this subject cannot be overemphasised

Kerosene (synonymous with paraffin) is rather a loose word which is representative of liquids that can be made up of widely differing components, but broadly speaking, kerosene consists of those fractions of petroleum boiling in the approximate range of 175–275°C The fractions are made up of varying mixed proportions of paraffins and naphthenes These hydrocarbons fall within the groups of branched paraffins, monocyclic and di-cyclic naphthenes, and mixed aromatic napthenes in the range C 12–C 15 Moderate quantities of unsaturated cyclic compounds may also be present I think it might safely be stated that the toxicity of kerosene depends upon its content of naphthenic and aromatic hydrocarbons These would vary in type and proportion with the place of origin of the parent crude oil I lay considerable stress on this latter statement, since obviously it is of importance, furthermore, I think there is general agreement that there is a paucity of information regarding the toxicity of naphthenic acids This indeed is rather surprising, in view of the large extent to which these chemicals are used within and without industry

Kerosene is marketed in this country in three grades

1 *Tractor kerosene, or vaporising oil*—This is used almost exclusively for tractors, and contains mixed aromatic naphthenes to the extent of some 23% by weight These naphthenes are in the range C 12–C 15

2 *Premium, or household kerosene*—This type of kerosene is that which has been refinery treated by the Edeleanu process Put simply, treatment with this process entails the removal of aromatics, nevertheless some 7% by weight remain

3 *Regular grade*—This grade is used as aviation turbine fuel and is also used for domestic heating The aromatic content of this fuel is approximately 15–20% by weight

The aromatics referred to contain some benzene and homologues of benzene, these latter with a multiplicity of side chains (e g, methyl-benzene (toluene), butyl-benzene, di-iso-butyl benzene, di-iso-amyl benzene, tetra-methyl-benzene, penta-methyl benzene, and hexa-methyl benzene) In so far as I am able to ascertain little is known regarding the toxicology of these aromatics, but I feel that the chemical make-up of these compounds should immediately put them under suspicion in respect of their toxicity In addition, there are traces present of di-phenyl methanes, alpha and beta methyl naphthalenes, ethyl-propyl, iso-propyl, iso-butyl, and iso-amyl naphthalenes Once again, little is known regarding the toxicity of these materials

The cyclo-paraffins in general are rather powerfully narcotic, and can cause death by respiratory paralysis However, the outstanding feature of these paraffins is the extremely small margin between concentrations required to produce unconsciousness and concentrations causing death I believe that this small margin is largely one of the reasons why these paraffin hydrocarbons are not more generally used as anæsthetics The aromatic cyclo-paraffins, which of course contain the six-carbon-atom benzene ring, also produce anæsthesia, narcosis, and ultimate death, and here again the margin between narcosis and death is extremely small Furthermore, the anæsthetic and narcotic action of these materials increases the higher the position of the fraction within the group

---

[15] Stewart J S S *Acta endocr, Copenhagen* 1960 33, 89
[16] Ashley D J B, Jones C H *Lancet* 1958, i 74
[17] Ohno S, Kaplan W D Kinosita, R *Exp Cell Res* 1959, 18, 415
[18] Nowakowski H, Lenz, W, Parada, J *Klin Wschr* 1958, 36, 683

In view of the foregoing, encouragement of rapid evacuation of ingested kerosene seems to be desirable, since surely it is easier (particularly with the range of antibiotics now available) to deal with an aspiration pneumonitis or pneumonia, rather than attempt to deal with the possible absorption of chemical materials, the toxic properties of which are almost unknown. The three positive measures recommended in the article (e.g , ingestion of vegetable oil or ice-cream to dilute the kerosene and diminish the rate of absorption into the blood), I would question because quite possibly diminished rate of absorption might well mean greater perfection of absorption. I would also point out that kerosenes of all three grades are distributed throughout the world in large quantities and I feel that emergency measures to combat intoxication should be very carefully assessed to ensure their ultimate success

B GEORGE

CADWALADER AND BEVAN

SIR,—In their paper of March 19, Dr Fourman and his colleagues mention what is undoubtedly the first clinical description of hyperparathyroidism—that of Thomas Cadwalader of Philadelphia, whose account of his "extraordinary case in physic" was published in 1745

Ralph H Major[1] includes Cadwalader's essay in his volume *Classical Descriptions of Disease* (3rd ed., 1945, pp 299–302), but is presumably in error in interpreting the account as "the first description of mollities osseum, or osteomalacia" Krumbhaar[2] rightly emphasises the historical significance of Cadwalader's description as the original clinical picture of primary or secondary hyperparathyroidism.

Dr Fourman includes the name of one Bevan, S , in his list of references, this was Silvanus Bevan, a London apothecary, who, in a letter to the Royal Society in 1743, described a similar clinical condition. At first sight this seems to anticipate Cadwalader's account, but in fact the cases were identical Cadwalader performed the postmortem examination on his "extraordinary case" in April, 1742, subsequently informing Bevan of his findings, Bevan thereupon reported them in his letter to the Royal Society

The modern pharmaceutical firm of Allen & Hanburys originated in the apothecary's shop opened by Silvanus Bevan at Old Plough Court, off Lombard Street, in 1715 In their historical account of this company, D Chapman-Huston and E. C Cripps[3] referred to Bevan's letter, but they wrongly assumed that Bevan himself performed the postmortem examination, the error arising from the fact that Bevan's original letter to the Royal Society contained the phrase "communicated to Silvanus Bevan", a phrase that was not included in the subsequently published Transactions

Thomas Cadwalader and Silvanus Bevan were both members of Welsh Quaker families, many of which were closely knit and interrelated following the religious persecution of their sect in Wales in the latter half of the seventeenth century Cadwalader probably met Bevan in London when he came to Europe to further his medical education under Cheselden during the years 1728–30 On his return Cadwalader became a prominent figure in the medical circles of the growing town of Philadelphia, then the largest in the colonies Among other things he inaugurated anatomical classes and successfully promoted the use of inoculation for smallpox, he also established, in association with Benjamin Franklin, the Philadelphia Hospital

I contributed an account of the associations between Cadwalader and Bevan, and of their original descriptions of hyperparathyroidism, to the Welsh quarterly periodical *Y Genhinen* in 1955[4] In the same paper I attempted to show that several of the descendants of Welsh Quaker emigrants had made notable contributions to the growth of American medicine, prominent among them Thomas Cadwalader, his young associate John Morgan, and his cousin John Jones[5]

Caernarvon.

G PENRHYN JONES

LATEX AGGLUTINATION REACTION IN NON-RHEUMATIC DISEASES

SIR,—In your annotation of March 26 you stated that the latex test (L T) and the Rose-Waaler test (D.A T) were approximately equal in sensitivity, and that the L T lacked the specificity of the D A T , being positive in a wide variety of unrelated non-rheumatoid conditions

May I draw your attention to a recent article of mine[6] in which I described a series of L T S and D.A T S in 176 cases of rheumatoid arthritis and non-rheumatoid conditions. In the R.A. group, 89% of the L T S were positive, while the D.A.T S was positive in only 74% of the cases 3 out of 6 cases of disseminated lupus erythematosus gave positive results in the D.A.T while all 6 cases gave negative results in the L.T.S Furthermore in 47 cases of non-rheumatic disease, the L.T was persistently negative, and no false-positive results were seen in the series

Singer and Plotz[7] described a series of L.T S carried out in tubes, in which 71 3% of rheumatoid-arthritis cases gave positive results The present series was carried out using latex globulin particles and a simple slide technique, and the probable reason for a higher percentage of positive results (89%) is that the reagents used were superior and more stable

London, N 15

G MORGAN

AN EASIER ALPHABET

SIR,—Dr Pugmire's article of March 26 was refreshing in its lucidity and reflects a satisfactory tendency to place neuropsychiatry on a scientific basis However, I feel that the issues involved are more complex than may appear from his discussion

The main reason for designing the "six-bit" alphabet seems to have been a wish to reduce or abolish the redundancy of written English On the face of it a redundancy of the order of 50% does seem wasteful, since it means that more signal is uttered than is needed to express the Information of the message with complete economy But all methods of computing the redundancy of language (and there are several) involve an exact and often laborious statistical analysis of the sample, at leisure. That is, the "recipient" of the language in these circumstances has time to function at something like 100% efficiency In practice, on the other hand, the recipient of spoken or written language is nearly always under the pressure of haste to some extent It is well known that the risk of error increases with the rate of performance, with many intellectual tasks In short, it is likely that in normal conversation or reading (as opposed to statistical analysis) the recipient is functioning at less than 100% efficiency and is not extracting from the language all of the Information potentially extractable. It is an accepted principle of communication theory that redundancy serves to protect against errors in transmission, one may therefore regard the redundancy of English as a compromise between "writer's economy" and "reader's economy", and also between the policies of saving time on the one hand and of avoiding loss of Information on the other

By reducing redundancy Dr Pugmire has developed a highly compact script. If the reader is to extract the same amount of Information from a sentence written in this script as when it is written in the more redundant ordinary script, he will either have to spend more time per symbol or else increase his rate of Information-handling (i e., "concentrate harder") Mentally defective or brain-damaged patients probably have less reserve capacity in hand for such tasks, and for them it seems doubly likely that redundancy is an important feature of language, "speaker's economy" and "writer's economy" must be sacrificed in the interest of the recipient Who has not had to say the same thing over and over again to a stupid listener, in order to din it in?

---

[1] Major, R H Classical Descriptions of Disease, pp 299–302. Springfield, Ill., 1945

[2] Science, Medicine, and History, p 138 Edited by E Ashworth Underwood. Oxford 1953

[4] *Y Genhinen*, 1955, 5, 86

[5] *Bull Hist Med* 1943, 13, 10 1948, 22, 543

[6] *Ann rheum Dis* 1959 18, 322

[7] Singer, J M., Plotz. C. M *Amer J Med* 1956, 21, 888

A case might, in fact, be made out for designing a language with *high* redundancy for certain circumstances It is partly a matter of deciding how much importance to attach to speed and to freedom from error in any given case Temperamental factors must play a part here, since obsessional subjects will tend to go slow rather than risk a mistake, while others may adopt a more breezy attitude We must also distinguish between redundancy in the symbolic representation of language (with which Dr Pugmire is dealing) and in the linguistic representation of thought It may be that redundancy in the script is only "protective" in cases where the defect lies in the perception and recognition of written symbols, rather than in the comprehension of words

Let us beware of developing too condensed and efficient a language, lest it should become as spare and austere as those of formal logic and algebra It would be a pity to increase the already large proportion of relatively illiterate people in the population

University College Hospital
Annexe, London, W 1

H B G THOMAS

TREATMENT OF BEDSORES

SIR,—I was very interested in Dr Roberts' letter of Jan 30, and, as he has given the formulæ of these two creams, I will refer to them as cream I or cream II

Although we have 245 patients in our hospital, about 30% of whom are bedridden and many incontinent, we have not got many bedsores We alternate the treatment by using our own "back" ointment, which consists of tinct. benzoin co and ol ricini (28 oz of each) and paraffin molle flav, ung zinci oxidi, and ung acidi borici (equal parts of each) to 14 lb, or painting bedsores with gentian-violet, or using silicone cream I or II

In 6 special cases our ordinary treatment showed no improvement, but in 5 of them the results of cream II were really dramatic and the bedsores healed within seven to ten days

We have used cream I or II in about a dozen other bad cases without much improvement, but I would like to mention that most of these patients were suffering from either paralysis agitans or disseminated sclerosis, and naturally their general condition was very weak. It is very difficult to give a decided opinion with only 18 cases, but on the whole our experience is that cream II gave better results

Both creams used in the trial were kindly supplied by Messrs Ward, Blenkinsop, and my committee and I wish to thank them very much for their liberal supplies

Royal Hospital for Incurables,
Donnybrook, Dublin

ROBERT A O'MEARA

PERIORBITAL ŒDEMA AFTER EXERTION

SIR,—I recently saw a young man, aged 19, who had an interesting history

Since childhood he has occasionally had acute swelling of his eyelids after exercise This intense œdema sometimes causes almost complete closure of both eyes This curious complaint prevented him from playing games at school, and has interfered with his activities in the Army

The amount of exercise precipitating an attack is very variable The condition does not seem to be correlated with excessive facial sweating, and he has noted no seasonal variation There was no history of allergy

He was recently seen during an attack. Both eyelids were acutely swollen, and in addition he had bilateral chemosis The latter rapidly disappeared with hydrocortisone drops Anti-histamines do not prevent attacks

He had moderate acne on both sides of his face, but general examination was otherwise quite normal Examination of his blood and urine, and X-ray of chest and skull, were normal.

I should be interested to know whether any of your readers have seen this unusual syndrome and can suggest a possibl ætiology

Tidworth, Hants

D P MULLAN

ABDOMINAL ANEURYSMS

SIR,—Concerning your annotation[1] on this subject, while it is agreed that the question of operation for every clinically detectable abdominal aortic aneurysm has not been settled, the facts on which you base your statement that "it is hard to substantiate the common belief that any abdominal aneurysm which can be diagnosed should be resected" are not valid

(1) You cited the article of Estes[2] and stated, "Many died of aneurysmal rupture, but more died of coronary or cerebral thrombosis" This is not true Estes ascertained the cause of death in 49 of the 64 patients in his series known to be dead and reported that 63 3% of these 49 patients died from rupture of the aneurysm, while the remainder died from other causes Thus, most of his patients died because of their aneurysms rather than with them

(2) In considering the work of Sheranian and associates[3] on their experience with aortic homografts, you stated, "At operation only 110 of the 135 aneurysms were resectable" This is not the case These authors clearly stated that only 10 of these cases were considered inoperable at the time of exploration They stated further that another 15 cases were excluded from the series because the aneurysm was resected and replaced with a synthetic graft Thus, you have included these 15 cases as being inoperable when, in fact, these aneurysms were resected and replaced with synthetic prostheses instead of homografts

(3) Since the object of your annotation was to consider whether elective operation for abdominal aortic aneurysm was indicated in all cases, it is not fair to include the 6 cases in the series of Sheranian and coworkers in which emergency operations were performed because the aneurysm had ruptured The mortality-rate in these 6 cases was 50%

(4) You then say, "if it is assumed that in the 25 advanced cases where resection proved impossible at laparotomy the patients were dead" (at the end of three years), here again, we are dealing with 10 inoperable cases, not 25 It is probably invalid to assume, as you have, that all of these patients in whom resection was impossible would be dead at the end of three years Estes found that 49 2% of patients with untreated abdominal aortic aneurysms survive for three years Since the patients who have inoperable lesions are essentially untreated patients, there may well be only 5 of these patients with non-resectable aneurysms dead at the end of three years, not 25

We do not dispute the fact that surgical intervention for abdominal aortic aneurysms must be carefully considered Comparison of patients with surgically treated abdominal aortic aneurysms to a similar group of patients not treated surgically, with both groups being followed for a sufficient period, would be the best way to tell whether surgical intervention is more dangerous than observation Until such is done, however, your conclusions cannot be validated by your premises

Mayo Clinic,
Rochester, Minnesota

IRWIN J SCHATZ
JOHN L JUERGENS

*** We are grateful to Dr Schatz and Dr Juergens for pointing out these lapses Despite our arithmetical weaknesses, we believe our two main points still hold (1) it is not known how many aneurysms were turned down before Sheranian selected the ones to be operated on, and (2) it is not justifiable to assume that every abdominal aneurysm diagnosed should be resected As Dr Schatz and Dr Juergens emphasise, until it has been possible to compare directly the results of surgical and conservative treatment it would be wrong to declare that operation is always indicated —ED L

CORTICOSTEROID PURPURA

SIR,—We were extremely interested in Professor Lovell's comments (March 5) on our preliminary communication and regret the omission of reference to his work on the effect of corticosteroids on the resorption of blood.[1] Unfortunately, it was not possible to present all of our experimental evidence in a short communication but we hope to do this in a future publication

Professor Lovell's suggestion is that the delayed resorption of blood from the skin produced by corticosteroids is due to a diminished dispersal of blood between the collagen fibres rather than to suppression of phagocytosis We are unwilling to accept his view for two reasons The first is that increased spreading of blood through the skin is characteristic of both corticosteroid purpura,[2] and also of senile purpura The second is that the role of the phagocyte in promoting the resorption of extravasated blood has been described by Rich,[3] and further, that the different rates of resorption of blood injected into the skin of the rabbit, rat, and mouse appear to be due to a species difference in the phagocytic response[4] It is possible, therefore, that the sluggish phagocytosis of erythrocytes found by Lovell et al in the guineapig may be a peculiarity of this species

The Royal Infirmary,
Cardiff

H SCARBOROUGH
S SHUSTER.

MERIT AWARDS

SIR,—Those recommendations of the Royal Commission which relate to merit awards serve to highlight the figures you published last year[5] At that time, the expectation in cash from merit awards to a consultant physician or surgeon was more than £590 a year To a consultant in mental health it was a little more than £130 If the recommendations of the Commission are adopted without changes in the proportionate distribution of the awards, the figures I have given would become approximately £780 and £180 The figures as they stand also show that the consultant physician or surgeon is more likely than not to have some award, his chance of a higher award is more than six times that of the psychiatrist, consultant anæsthetists alone of all specialists have as low a chance as the psychiatrist of gaining some award (Royal Commission, p 76)

The probability of such disproportion arising by chance in even one year is so small as to be almost beyond computing. It is certainly much less than one in a thousand. For awards grouped in a two-by-two contingency table (some award, no award, psychiatrist, and physician or surgeon) chi-square with Yates' correction is 17 1 with one degree of freedom, and for the higher awards chi-square runs to three figures An assessment over the whole life of the service would give an incomprehensibly small figure for the probability of chance occurrence of the disproportion.

If any of the unrecognised 85% of consultants in mental health are inclined to accept an association between merit awards and clinical ability, they may, perhaps, console themselves with the reflection that they are practising one of the most difficult of the medical arts, and they will no doubt keep an eye open for the effect of a psychiatrist having been appointed to the committee on these awards

PEPTIC ULCER IN TOWN AND COUNTRY

SIR,—I have studied with interest your editorial of Feb 27, especially as you stress that Pulvertaft, probably for the first time, has estimated ulcer frequencies accurately in an unselected population

I should like to draw your attention to the investigations in 1950-52 by one of my assistants, N Sponheim.[1] He made similar inquiries in a part of a Norwegian county During a period of $2^1/_2$ years 811 ulcers were found in a population of 124,279 All ulcers were verified by expert X-ray examinations

The mean annual incidence per 1000 population aged 10 years and over was 4 0 in men, and 1 2 in women. In males the incidence was found to be highest between 30 and 39 years of age—i.e., 6 1, and in females highest between 40 and 49—i e , 2 0

PER HANSSEN

ADENOVIRUS TYPE-15 AND HUMAN-THYROID TISSUE-CULTURE

SIR,—Adenovirus type-15 was originally found in conjunctival scrapings from 5 babies in Saudi Arabia during field studies on trachoma,[2-4] and it does not appear to have been reported elsewhere until now

The first of 2 patients from whom the virus was isolated in this laboratory was a 7-month-old baby who was admitted to this hospital in March, 1959, with severe diarrhœa complicating a pyrexial upper respiratory illness An adenovirus was isolated from her fæces, and no specific bacterial pathogens were cultured from repeated stool specimens An adenovirus was later isolated from the stool of a 6-year-old girl with a *Salmonella typhimurium* infection admitted to the same ward shortly after the first patient. The second child may have been cross-infected from the baby Both these strains failed to react in this laboratory with typing antisera against adenoviruses types 1 to 8 Dr H. G Pereira very kindly offered to examine them and found them both to be type-15

These 2 isolations of adenovirus type-15 were made in human-thyroid tissue-culture. Pulvertaft and his colleagues,[5] who first described thyroid tissue-culture, considered that because of its susceptibility to toxic factors in fæces it probably would have a place in virus isolation from stools only if monkey kidney or human amnion were not available. In this laboratory it has proved a valuable addition to monkey kidney From January to December, 1959, 650 stool specimens were tested in parallel in human-thyroid and monkey-kidney tissue-cultures Toxicity of stool extracts for thyroid tissue caused little trouble. Of 143 viruses isolated, 37 were isolated in both tissues, 28 in kidney but not in thyroid, and 71 in thyroid but not in kidney The 71 viruses grown only in thyroid include 10 adenoviruses—of types 1, 2, 3, 5, 7, and 15—and 61 enteroviruses including Echo types 6, 7, and 11 and Coxsackie B5 Many of the enteroviruses not yet fully typed appear to be Coxsackie viruses Most of the enteroviruses were recovered from patients with aseptic meningitis

Thyroid was found to equal HeLa cells in susceptibility to all of 16 prototype strains of adenovirus examined, and in addition was as sensitive as fresh monkey-kidney tissue to infection by the 3 types of poliovirus and by 18 of the 28 prototypes of Echo virus Echo 21 and 28 were not tested, Echo 25 gave a lower titre in thyroid than in kidney, and Echo types 4, 10 (not now classified with the Echo group[6]), 14, 15, 16, 25, 26, and 27 failed to produce any cytopathic effect in thyroid. The susceptibility of thyroid tissue to both adenoviruses and enteroviruses, its slow rate of metabolism enabling it to remain for up to 3 weeks without requiring a change of medium, and the readiness with which it can be obtained, make it a valuable tissue in diagnostic virology

HÆMORRHOIDS

SIR,—Your editorial of Feb 20 suggests only surgical or injection treatment for hæmorrhoids

In the past year I have followed 27 cases of hæmorrhoids and pruritus ani treated locally with a new preparation, 'Alcos-Anal', and in all but 3 the results have been very good In the successful cases, after four weeks' treatment hæmorrhoids disappeared, and after six months there were no recurring symptoms Large hæmorrhoids with prolapse were not included in the trials

Alcos-anal ointments and suppositories contain the sodium salts of unsaturated fatty acids of cod-liver oil, substances which have long been used for the intravenous obliteration of varices and hæmorrhoids

Similar trials during the past five years have shown equally good results [1-3]

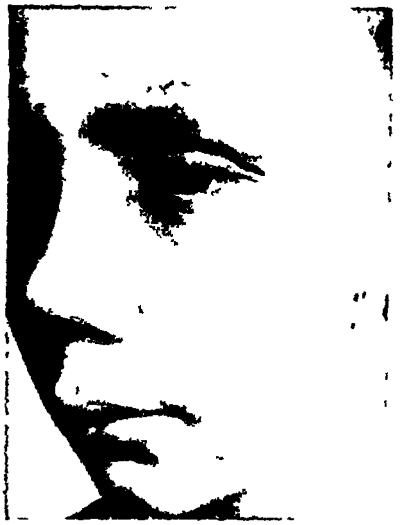
TREATMENT OF SKIN LESIONS BY HYPNOSIS

SIR,—Dr Sinclair-Gieben and Dr Chalmers (Oct 3) are to be congratulated on their excellent article, originality, and carefully controlled trials I was, however, astonished at the statement that "after several hypnotic sessions a relationship vaguely resembling a transference situation is established" A transference relationship occurs between any two people that meet, especially in the association of patient and doctor, where the patient comes to receive and his adviser is there to give The failure of two patients to reattend after one session shows this—a negative transference, a rejection, mistrust, fear, and resentment of the hypnotist It is the enhancement and utilisation of the transference that gives good results in hypnosis, but, with explanation of the transference, excellent results in hypnotherapy



A boy aged 10 had pityriasis lichenoides (see figure) I was reassured by two dermatologists that the condition was benign, liable to spontaneous remission, unresponsive to any treatment, might be helped by ultraviolet light, and might last a long time Unfortunately, both the patient and his mother were not so reassured Early this year I began regular weekly sessions of hypnosis, at first of half an hour, and later five minutes in surgery hours The child's morale and skin improved, the lesions fading from the body in the order I suggested. Treatment ceased abruptly at the start of school holidays in July

When I returned from holiday in September, his enti rash had recurred Since that time in three half-hour sessio his skin condition has again dramatically improved. His fa is almost without blemish Two factors are apparent her Firstly, that his setback occurred when his whole body ha been exposed continually to the glorious sunshine, and at th same time there was a dramatic break in a strong positiv transference Secondly, that like warts, this condition benign, liable to spontaneous remissions, and helped by dee hypnosis Most people would agree with Bloch and you contributors that the cure of lesions by hypnosis does *not imply* their psychogenesis My own impressions, gained *especiall* from adolescents with plantar warts, is *completely* contrary

Dr Sinclair-Gieben and Dr Chalmers state that th most responsive patients were in the *second and* third decades of life This may give an erroneous impression of the efficacy of this treatment in children, who are excellent subjects

It would be of interest in further trials to compare the effect of suggestion on the opposite sides of the body Our left side, *the bad* side compared with the right (sinistre and droit), is said to be more directly under the influence of the unconscious in right-handed people It would be of interest to know in their case where the untreated side showed spontaneous disappearance six weeks after the treated side, which side had received suggestions, and what the patient meant by flouting the authority of his doctor and curing himself!

I am much indebted to Mr A C Bingold for the photograph

Sidcup, Kent

L A NICHOLS

BISALBUMINÆMIA

SIR,—Mr Franglen and his colleagues (Feb 6) raise many interesting points in their paper concerning "bisalbuminæmia"

We have a communication in the press (*Clin chim acta*) about another family with that anomaly We too attempt a genetic explanation but point towards analogy with sickle-cell trait

Franglen et al 's hypothesis concerning persistence of a fœtal albumin does not agree with our findings, the mobility of the extra albumin we found to be slightly greater than that of normal adult serum-albumin

A review of the literature clearly shows that at least two types of "bisalbuminæmia" occur In one group the extra albumin has a mobility that is higher than that of normal adult serum-albumin, in another group that mobility is lower In all these cases, however, a protein seems to be present whose mobility is identical to that of normal serum-albumin It accounts for rather more than 50% of total albumin Both points are in favour of the sickle-cell-trait analogy

We wish to emphasise the importance of accurate measurements of mobility and percentage of both albumins in further studies concerning this hereditary anomaly

SALMONELLA OSTEITIS

SIR,—The article (Jan 9) by Dr Hendrickse and Professor Collard on salmonella osteitis interested me I wonder whether the *Salmonella enteritidis* cases were not due to "transient bacteræmia" but were actually late complications of the specific infection caused by *Salm enteritidis* var *chaco*

Cosgrove and Reid [1] described 17 cases in Sierra Leone. In 2 bone infection developed Like enteric fever it starts as a septicæmia with sudden onset of headache, vomiting, and diarrhœa There is a sharp rise in temperature to 101–103 F, *maintained for* 10 days, and then the fever subsides by crisis or steep lysis Recovery is complete unless localisation with pus formation occurs—usually after the 10th day This is accompanied by a swinging temperature and leucocytosis Early diagnosis depends on blood-culture. Later the organisms may be isolated from the fæces or pus The Widal reaction can be misleading, because the O antigens of *Salm typhi* and *Salm enteritidis* are similar and cross-agglutination is frequent.[2]

---

[1] *Med Klin* 1953, 48, 176
[2] *Münch med Wschr* 1953 95, 805
[3] *Brit & Overseas Pharm Med* 1959, 112, 254

[1] Cosgrove, P C., Reid J D *Trans R. Soc trop Med Hyg* 1953, 47, 153

Salm enteritidis var *chaco* has been reported from the Gran Chaco, China, India, and New Guinea and is probably more prevalent than is realised No special attention was paid to the presence of the sickle-cell trait in our series

THE CARPAL-TUNNEL SYNDROME

SIR,—It was most interesting to read Dr Moss's observations on the carpal-tunnel syndrome (March 26) He observed that these symptoms are often associated with rheumatic manifestations

In the course of an investigation of "fibrositis" and muscular rheumatism in relation to psychological stresses, during which the activity of individual muscles was estimated by palpation and manual muscle testing,[3] a patient was seen who had pain and paræsthesiæ in the area of distribution of the median nerve only when the pronator teres was tense The symptoms were attributed to compression of the median nerve between the superficial and deep heads of the muscle, and were produced only when the arm was semi-flexed and pronated (overtly or covertly)

Other patients were seen with complaints of similar symptoms in the area of distribution of the sciatic nerve during tension of either the biceps femoris or the soleus compression of either the sciatic or the posterior tibial nerve by the overlying muscle was thought to be the most probable mechanism [4]

Such findings raise the question of a psychological aspect being operative when any physical therapy is employed to relieve "fibrositic" pain, or paræsthesiæ of uncertain origin

EFFECT OF AGE ON RELATIONS BETWEEN PARATHYROID AND PITUITARY

SIR,—The parathyroid glands of young and adult white rats have been studied morphologically in normal, hypophysectomised animals and animals treated with hormones according to the method described earlier [5]

Gland function was assessed histologically by means of nuclear and cellular volumes, degree of clearing of cytoplasm, and frequency of mitosis Cellular and especially nuclear swelling, with a widespread increase in clear chief and water-clear cells and an increase in mitotic figures point clearly to hyperfunction of the gland, and the opposite findings suggest hypofunction.[6] The following conclusions can be drawn for both sexes

(1) The parathyroid glands of normal young animals show larger nuclei, definite cytoplasmic clarification, and higher mitotic frequency than normal adult controls

(2) As in adults, growth hormone enhances parathyroid hyperfunction even in young rats

(3) Corticotrophin (A.C.T H) does not affect adult parathyroids, but it depresses parathyroid function in the young

(4) Hypophysectomy has no influence on adult glands, but consistently slows down the activity of young parathyroids, as judged histologically

(5) Replacement therapy with growth hormone after hypophysectomy increases parathyroid activity in adults, but it is unable to modify hypofunction due to hypophysectomy in young rats

University of Pavia Italy

LEONARDO MOSCA

PLACENTA PRÆVIA

SIR,—I must thank Mr Percival and Dr Murray for their letter of March 12 and the compliment paid to me in the first two sentences

I am afraid I am still unrepentant regarding the retention in hospital of any patient who has had an episode of bleeding between 30 and 37 weeks One cannot tell, without retaining the patient for more than eleven days, if the episode will recur Mr Percival and Dr Murray state "This surely does not lie comfortably beside what he originally said about the expectant management of placenta prævia in 1945" I admit that it does not. While the statement I made then was based on what I regarded as sound clinical observation, I would not practise it today after a further fifteen years' experience

In the past fifteen years I have been impressed with the high fœtal mortality associated with antepartum hæmorrhage of unknown origin In a series of 360 cases of accidental hæmorrhage treated in the Royal Maternity Hospital, Belfast, 245 were of the non-toxic or unknown-origin type In the latter group the fœtal mortality was 27 3% although only 29% had recurrent hæmorrhage The figure of Miss Josephine Barnes for this group in 1945 was 27 8%

Over the past few years all cases of antepartum hæmorrhage have been retained for investigation, and I hope when these cases are reviewed this attitude will be justified The cases to which Mr Percival refers "hardly amount to antepartum hæmorrhage" and I presume can be safely treated like a threatened miscarriage I see very few such cases, and if I did, would probably do the same as Mr Percival, basing my treatment on clinical methods especially in primigravidæ.

Mr Percival and Dr Murray criticise me for not mentioning some very important issues in referring to the discussion in the Royal Society of Medicine in January, 1959 As you know, Sir, the article you published was an abbreviated version of my original lecture In fact I am very conscious of the possible value of *accurate* soft-tissue radiography in diagnosing placenta prævia before the patient has had any hæmorrhage The possibility of a placenta prævia must always be considered in any patient with a high free head at or near term, and any experienced obstetrician investigating such a case will be very conscious of the necessity for careful abdominal and vaginal examination in the appropriate surroundings

We must, however, be realistic about soft-tissue radiography I quoted Dr Blair Hartley and need not repeat, but most obstetricians throughout the world have not got accurate soft-tissue radiography at their command and must depend on careful clinical examination and assessment A large percentage of my audience on this occasion fell into such a group, and I feel sure that careful clinical examination associated with clinical experience is more valuable than poor radiography

In my original lecture I noted and acknowledged that Mr Stallworthy had supplied me with the quoted figures from Oxford In rewriting and reducing the lecture for publication this acknowledgment was accidentally omitted I offer him my apologies for this oversight

Institute of Clinical Science,
Queen's University of Belfast

C H G MACAFEE

*** We apologise to Professor Macafee for misunderstanding his intention and publishing last week a letter which he intended to supplement not replace the earlier one which he sent us on March 14 and which appears above —ED L

SIR,—In view of Professor Macafee's courteous and over-generous reply (April 2) to my letter of March 19 I hesitate to ask for more of your space, but one of his statements requires an immediate answer He states "As we do not know the extent of the risk to which we submit the unborn child when we expose it to X-rays (and some authorities state that it is considerable), it is doubtful if exposure for four films is justified "

---

2 Reid, J D *West Afr Med J* 1953, 11, no 2.
3 Draspa, L J *Brit J med Psychol* 1959, 32, 106
4 Draspa, L J Ph.D thesis, lodged with the University of Edinburgh, 1955
5 Mosca, L *Quart J exp Physiol* 1957, 42, 267
6 Engfeldt, B *Acta endocr Copenhagen*, 1950, suppl no 6, Platt H *J Path Bact* 1950, 62, 383 Eder, M., Hartl F *Beitr path Anat* 1955, 115, 470, Lever, J D *J Endocrin* 1958, 17, 210

Will Professor Macafee please give precise references to the authorities who still state that the risk is considerable? My information is exactly to the contrary It is agreed that there *may* be a risk, but even that is not proven If there is a risk it must be an exceedingly small one

This statement is made having heard Dr W R Doll and Dr W M Court Brown reading their paper to the Section of Epidemiology and Preventive Medicine at the Royal Society of Medicine on March 18 As I understood it the gist of their paper on "studies on the possible effects of low doses of radiation" was to the effect that they were very nearly able to state that their investigations showed that there was no risk, but that for statistical reasons and in order not to overstate their case they were prepared to go only as far as to say that if there be a risk it must be extremely small

I think it is important too to recognise the fact that the interim report of the Committee on Radiological Hazards to Patients (now widely known as the Adrian Committee) took pains to state that they considered it advisable to produce an interim report, saying

> "We do so because the hazards of ionising radiation have been widely publicized and there is some danger that radiological examinations and radio-therapy of every kind will be viewed with unnecessary suspicion by the public at large, so that the individual patient may come to harm through his reluctance to be X-Rayed"

Furthermore on p 9, para 31, the committee states

> "Particular attention ought to be paid to X-ray examinations of pregnant women Obstetric X-rays for pelvimetry, determination of placental site, or fœtal maturity for example *are of proven value* in conserving the lives of mother and child, but should not be undertaken as a routine procedure in every case When specifically indicated, however, there should be no hesitation about their employment"

We are all agreed that all ionising radiations must be skilfully used and are not to be employed wantonly, but no informed person within my knowledge has ever suggested that any risk which there may be outweighs the benefit of X-ray examination, where there is a clinical reason for inviting examination by the X-ray method

J BLAIR HARTLEY

ROLE OF FUNDUS IN PREVENTION OF GASTRO-ŒSOPHAGEAL REGURGITATION

SIR,—It was with considerable interest that I read Mr Goldberg's article of March 19, and I should like to suggest that his technique should not be regarded as "an experiment"

Dissatisfied with the high recurrence-rate using either the thoracic or the abdominal approach, I have for some time now used an operative test of competence of the gastric cardia The technique used is exactly as described by Mr Goldberg with the exception that I rely on introducing a measured quantity of fluid into the stomach before and after displacement of the gastric fundus, and so dispense with radiology In the steep Trendelenburg position reflux of fluid, which is very free before repair, should be absent after insertion of the displacing sutures If reflux still persists suitable adjustment can be made before conclusion of the operation

Competence can be obtained more easily if bilateral subdiaphragmatic selective vagotomy is carried out first This permits freer mobilisation of the lower end of the œsophagus from below, the restraining bow strings having been divided Vagotomy seems to be a justifiable procedure, as there is some evidence in our series that cases requiring surgery with œsophageal reflux have a high cephalic phase of gastric secretion.

Results using the above technique are encouraging as judged by preoperative and postoperative cineradiography

Hammersmith, London, W 6

A M B TOMPKIN

Parliament

The Budget

Introducing the Budget last Monday, Mr DEREK HEATHCOAT AMORY, the Chancellor of the Exchequer, declared that his aim was to consolidate the country's prosperity, and, as had been widely forecast, he proposed no striking changes Postwar credits are to be repaid to people who have been receiving sickness benefit or industrial-injury benefit for 26 weeks, and to all widows who are entitled to such credits in their own right Widows will also benefit from the new income-tax allowance of £40 for a widow or widower who has a child or children eligible for the child allowance and has no housekeeper This allowance will be made, too, to a single person responsible for young children with no housekeeper The dependent-relative and housekeeper allowance is to be increased from £60 to £75 Mr Heathcoat Amory puts the total revenue at £5958 million—£328 million more than last year "The things the nation wants—better education, up-to-date hospitals, and new roads—are all expensive, and if we demand them we must be ready to pay for them"

Offices Bill

At the committee stage of this Bill a provision was introduced to restrict the employment of women after childbirth At the report stage on April 1 this was modified to

> "the Secretary of State may provide by regulations for restricting the employment of women in offices after childbirth"

Mr DENNIS VOSPER, a joint under-secretary of State to the Home Office, said that this form of words would allow the Minister to provide different treatment for different circumstances He might for instance decide to make less provision for people employed on light work than on other forms of work Mr Vosper gave an assurance that the Minister would insert the word "knowingly" so that the employer should have the defence that he did not know that the woman had had a child within the prescribed period Even in this modified form Mr Vosper was unenthusiastic about the amendment because it incorporated into the Bill something which he was advised properly should be incorporated in due course in public-health legislation The Bill was read a third time and passed to the House of Lords

QUESTION TIME

School Dental Service

Mr T E DRIBERG asked the Minister of Education if he was aware of the deterioration of the school dental service in Barking, Essex, and what steps he was taking, in the light of the findings of the McNair Committee, to stimulate the recruitment of dental officers in this borough and in other places in which there had been a simultaneous increase in the number of dentists in private practice and in the incidence of dental caries among schoolchildren —Mr K P THOMPSON, parliamentary secretary to the Ministry, replied Yes, Sir, and I understand that the local education authority is doing all it can to recruit additional dentists The Minister of Health has in hand the implementation of the recommendations of the McNair Committee designed to relieve the overall shortage of dentists

Mr DRIBERG Is the Minister aware that of 1000 schoolchildren inspected in this borough last year, nearly three-quarters were found to need dental treatment, but that the last of the full-time dental officers left last year ?—Mr THOMPSON We share the hon Gentleman's concern about the situation We are in constant consultation with the Minister of Health and we will do what we can At the same time, I hope that parents will take what steps they can to see that their children get treatment by private dentists

Mr A W J GREENWOOD Are the facts given for Barking peculiar to Essex, or typical of the country as a whole ?—Mr THOMPSON They vary in intensity, but I am sorry to say that they are typical of the country as a whole

Radioactivity

Mrs JOYCE BUTLER asked the Minister of Health, as representing the Minister for Science, what was now believed to be the residence-time of fall-out in the stratosphere, and to what extent the figures of fall-out over Great Britain indicated that radioactive material was now virtually absent as a result of the voluntary suspension of hydrogen bomb tests —Mr DEREK WALKER-SMITH replied The time during which radioactive particles remain in the stratosphere following a nuclear explosion depends on the size, location, and time of year of the relevant nuclear explosion The lowest estimates have varied from 15 months for material injected in equatorial regions in recent years to 4 months for material injected in arctic regions in autumn, 1958 Measurements of radioactivity in air over the United Kingdom last autumn showed a very marked fall compared with earlier in the year, in part due to a seasonal decline.

Hospital Design Unit

Lord BALNIEL asked the Minister what studies had been prepared and published by the architectural, engineering, and medical design unit set up within his department in 1954 —Mr WALKER-SMITH replied A bulletin on operating-theatre suites was published in January, 1958 Bulletins on residential accommodation for nurses, consultative outpatient departments, and kitchens are in course of preparation, as are some engineering studies and interim building notes on several other hospital departments An outpatient department and kitchen are to be built as the first of a number of development projects

Children in Prisons

Mr A. G BROWN asked the Home Secretary how many children under sixteen and seventeen years of age, respectively, were remanded to prison, instead of being sent to remand homes, in England and Wales, during the months of January and February, respectively, in 1960 Mr R A BUTLER replied In January there were so remanded 19 boys and 2 girls under sixteen years of age and 38 boys aged sixteen but under seventeen In February there were 37 boys and 4 girls aged sixteen but under seventeen

Obituary

JAMES MABERLY TAYLOR

M.R.C S

Dr J M Taylor, a member of the staff of the London Clinic of Psycho-analysis and a part-time consultant psychiatrist with the London County Council, died on Feb 15 at the age of 60

S B writes "James Taylor spent his teen years in the Sanatorium in Leysin and his early manhood in a section of the French Army during the first world war This made him bilingual and gave him access to French literature to which he devoted himself later at Oxford During the next few years, his love of letters found practical expression at Blackwell's In later years also, after qualifying from Barts in 1929, he often combined the skills of artist and artificer In this ability to master abstract and practical problems, he resembled his distinguished father, the surgeon-poet, John W Taylor Soon after establishing himself in general practice, James Taylor felt drawn to psychoanalysis, and later he qualified as an analyst. His practical sense and great artistic sensibilities promised a career of distinction in this specialty, but in his early fifties illness incapacitated him for some years, and when he returned to practice, his work was constantly interrupted by ill-health, despite his fortitude and the constant care of his wife, Dr Rosalie Taylor In recent years the fusion of theory and practice was manifested again in his work with maladjusted boys at the L.C C special schools, where many practical difficulties were successfully overcome Today, when the prevailing approach to medical problems is by the study of all-embracing biological principles, we can ill afford the loss of a physician who as a student of humanities was, in his practice of medicine, equally preoccupied with the intrinsics of Man"

Notes and News

AID TO HYDROTHERAPY

Mr Roy Maudsley, F.R.C.S, of Heatherwood Orthopædic Hospital, Ascot, sends us a description of a new aid to hydrotherapy

"Water has long been used to treat patients with trunk or limb paralysis or weakness, and the development of hydrotherapy pools in hospitals is increasing in this country The effect of gravity is reduced by the buoyancy due to the air within the lungs, but this has proved insufficient for many patients who have had this supplemented by air-rings around the chest, &c. These often prove cumbersome and necessitate close personal attendance by the physiotherapist. I have observed the advantages of a new method of buoyancy, similar to that recently introduced for yachtsmen and airmen

"The jacket or garment is of waterproof material, and is airtight except for a panel of special fabric which, when dry, allows air to circulate freely but, when wet, becomes watertight thus trapping the air in the garment. When the garment is dry again the air recirculates In practice, the jackets provide excellent buoyancy and give confidence to the patient, as well as making it possible for a physiotherapist to look after many more patients A floating mattress designed on the same principle can be used to support a patient in the water

"These garments have been designed by Mr Mark Shaw and are supplied by J Drew, 54-55, Dorset Street, London, W 1"

University of Cambridge

On March 19 the degree of M B was conferred on G H C Jenkins

University of London

On July 22 the university will commemorate the centenary of the award of its first degrees in science and the tercentenary of the Royal Society Among the fellows of the Society on whom the honorary degree of D SC. will be conferred on that occasion will be Sir Macfarlane Burnet, director of the Walter and Eliza Hall Institute for Medical Research and professor of experimental medicine in the University of Melbourne

University of Glasgow

On June 22 the honorary degree of LL.D will be conferred on Dr A K. Bowman, formerly senior administrative medical officer, Western Regional Hospital Board, Scotland, and Dr D P Cuthbertson, director of the Rowett Research Institute, Aberdeen

Royal College of Surgeons of England

Faculty of Anæsthetists—The Faculty will hold a scientific meeting on Saturday, May 7, at the college, Lincoln's Inn Fields, London, W C.2, at 10 30 A M The subject will be hypoxia, and the speakers will be Prof E A. Pask, Squadron-Leader John Ernsting, Dr. J B Brierley, Dr P D Bedford, and Dr B R J Simpson Further particulars may be had from the secretary of the Faculty

Scottish Regional Hospital Boards

The following doctors have been newly appointed to boards

South-eastern—A. G Cruikshank.
Western—Robert Black, D McKay Hart.

Royal College of Surgeons in Ireland

An honorary fellowship has been conferred on Sir Stanford Cade and fellowships on M P Brady and E J Gumey Licences in midwifery and surgery have been conferred on the following

Lesley J Clements, Michael Davy, Mohammed Moosa Jadwat, Sibertie Kissoon, D J O Brien, Hon Li Tai

Wellcome Trust

During the six months from Sept. 1, 1959, to Feb 29, 1960, the Wellcome Trustees accepted the following applications for major grants to assist medical research Together with smaller grants totalling £38,000, and travel grants amounting to £13,500, the total sum allocated by the trustees in the half year exceeds £400,000, or a total of over £800,000 for the last eighteen months

Major Grants

King's College, University of London (Prof J T Randall) £120,000 towards the purchase of the lease of premises to house a department of biophysics

University of Toronto (Prof C H Best) up to £70,000 to build and basically equip additional research accommodation in the Charles H Best Institute

Johns Hopkins Hospital, Baltimore (Prof A McGehee Harvey) up to £15,000 to adapt premises in the department of medicine as a research laboratory for studies of the heart and blood-vessels in man, especially by the method of X-ray cinematography

University College, London (Prof P B Medawar) up to £30,000 to build and furnish a research unit in cellular immunity as an annexe to the department of zoology

University College of the West Indies, Jamaica (Prof John Waterlow) up to £8000 to purchase a mass spectrometer for use in the Medical Research Council's tropical metabolism research unit

Prof A St G Huggett, St Mary's Hospital Medical School, London up to £2500 per annum for up to five years, to provide technical assistance and research expenses for work on the physiology of prenatal growth.

Electron Microscopes

Up to £34,000 to purchase four electron microscopes for use in the research programmes of Prof M G P Stoker, department of virology, University of Glasgow, Prof R E Coupland, department of anatomy, University of St Andrews, at Queen's College, Dundee, Dr John R Baker, department of zoology and comparative anatomy, University of Oxford, and Dr Paul Glees, department of physiology, University of Oxford

International Congress of Microbiological Standardisation

This congress will be held at Wiesbaden from Sept 5 to 10 The programme will include papers on poliomyelitis vaccines, measles vaccines, germ counting, and bactericidal and viricidal agents Further particulars may be had from the congress office, Marburg/Lahn, Germany, Postfach 167

Chronic Rheumatic Diseases

A course on this subject will be held at the Rheumatism Unit, St. Stephen's Hospital, London, S W 10, on Saturday and Sunday, May 14 and 15 The course will be opened by Prof C E Dent, and the speakers will include Dr Francis Bach, Dr Grace Batten, Mr R A Burn, Dr Philip Ellman, Dr W Frain-Bell, Dr F Dudley Hart, Mr Howard Jayne, Dr Philip Harvey, and Dr Gordon Signy Further particulars may be had from the secretary, Fellowship of Postgraduate Medicine, 60, Portland Place, W 1

Carlsberg-Wellcome Travelling Research Fellowships

Applications are invited for these fellowships for 1960–61 Their object is to encourage cooperation, on an exchange basis, between Danish and British research workers in any branch of the natural sciences which has a bearing upon human and animal medicine

One fellowship annually is awarded to a candidate from the United Kingdom for a year s work in Denmark and one annually to a Danish candidate for a year s work in the United Kingdom The stipend may range from £900 to £1300 per annum (or the equivalent sums in Danish kroner) travelling and some incidental expenses are provided in addition The tenure of the awards will start in September Further information may be had from the assistant scientific secretary of the Wellcome Trust, 52, Queen Anne Street, London, W 1 Applications must be submitted before April 30

Department of Health for Scotland

Dr W D Hood has been appointed deputy chief medical officer in the department in succession to Dr R J Peters who is retiring

Study of Hospital Meals

The Nuffield Provincial Hospitals Trust has made a grant of £27,500 to the London School of Hygiene and Tropical Medicine for a scientific study of the nutritive value of meals provided in hospitals Prof D D Reid, Prof R A Morton, and Dr F Avery Jones will serve on an advisory committee under the chairmanship of Viscountess Ridley It is hoped that Prof Harold Scarborough may join the committee on his return from abroad The study, which it is estimated will take up to three years, will be directed by Prof B S Platt

---

Dr R Y Caine, Dr Reginal Hall, and Dr I C Roddie have been awarded Harkness fellowships of the Commonwealth Fund tenable in the United States

A report of the meeting of the section of proctology of the Royal Society of Medicine and the American Proctologic Society held in London last summer has been published as a supplement to the *Proceedings* Copies (21*s* or $3) may be had from the society, 1, Wimpole Street, London, W 1

Two new standards for hospital pressure steam sterilisers have been published B S 3219 (1960) for horizontal cylindrical sterilisers covers six sizes ranging from 14 to 30 in in diameter, and B S 3220 (1960) for horizontal rectangular sterilisers covers four sizes, the smallest of which is 26 × 26 × 26 in Copies of these standards, 6*s* each, may be had from the Sales Branch, British Standards Institution, 2, Park Street, London, W 1

CHRISTIAN MEDICAL COLLEGE, VELLORE, SOUTH INDIA

CONSIDERABLE evidence has now accumulated pointing to some form of filarial infection as the cause of tropical eosinophilia (tropical pulmonary eosinophilia, eosinophilic lung) (*Lancet* 1958) It comprises the demonstration of a consistently high titre of filarial complement-fixing antibodies in the serum (Danaraj et al 1957, 1959), a consistent clinical, hæmatological, and serological response to therapy with the antifilarial, diethylcarbamazine (Danaraj 1958, Ganatra et al 1958, Baker et al 1959), and the experimental production of tropical eosinophilia in a volunteer by the subcutaneous injection of infective larvæ of two species of animal filaria (Buckley 1958) The blood is consistently negative for microfilariæ (Danaraj 1958), but microfilariæ have been demonstrated in the lymph-nodes of patients presenting with lymphadenopathy, and massive eosinophilia (Meyers and Kouwenaar 1939, van der Sar and Hartz 1945, Friess et al 1953) Some of these cases with microfilariæ in lymph-nodes have had respiratory symptoms and radiological evidence of pulmonary infiltration quite consistent with a diagnosis of tropical (pulmonary) eosinophilia. However, microfilariæ have never been identified in the lung lesions of this syndrome

In 1952 Beaver and his colleagues demonstrated in children in the Southern United States that invasion of internal organs by the larvæ of *Toxocara canis* was the cause of eosinophil granulomata in the liver, pulmonary infiltrations, and a massive eosinophilia in the blood These workers postulated that a similar mechanism of zoonotic helminthic infection might be responsible for tropical eosinophilia in India Three years ago a study was initiated by us to try and confirm this hypothesis

Two years ago, in a preliminary communication (Gault and Webb 1957), we reported the finding of what we then believed to be part of a nematode larva in the liver of a child with tropical eosinophilia. We now report the finding of microfilariæ in lungs, liver, and lymph-nodes of cases satisfying the diagnostic criteria of tropical eosinophilia (Ball 1950, Danaraj 1958) and describe the pathological changes in these tissues We also describe cases with involvement of lymph-nodes or liver but not lung

Material and Methods

Clinical Material

For the first four months of 1957, and again since July, 1958, all children seen at the Christian Medical College Hospital, Vellore, who were found to have eosinophilia of more than 4000 per c.mm have been seen by one of us (J K. G W) From among these children cases have been selected for further study

In the earlier phase of the investigation concern centred on the question of liver involvement and 5 children with typical pulmonary infiltration and moderate hepatomegaly were selected for open liver biopsy In addition, liver biopsy has been performed in 1 child with hepatosplenomegaly, but no lung or lymph-node involvement, and in 1 child with lymphadenopathy but no lung involvement

Throughout the period of the investigation, any opportunity to examine lung tissue has been taken. Tissue has been obtained in this way from a patient admitted under Dr S J Baker, an adult requiring pneumonectomy for a tension cyst of the lung, and from 1 child at the time of ligation of a patent ductus arteriosus 1 child was admitted specifically for lung biopsy In addition, one lung resected in 1950 and preserved in formalin was available for pathological studies

More recently, lymph-node biopsy has been performed in 12 cases—9 with pulmonary infiltrations, and 3 with no evidence of lung involvement.

Clinical Pathology

Absolute eosinophil-counts were done by the method described by Dacie (1956) Blood examinations for microfilariæ included several by the concentration technique described by Knott (1939) The method used for the filarial complement-fixation test (F.C.F.T.) was a modification of that described by Danaraj et al. (1959) Lymph-nodes obtained for biopsy were divided, some of the tissue was processed for histological examination, and some teased in normal saline solution and allowed to stand for several hours at room temperature, the centrifuged deposit then being examined for microfilariæ both in wet preparations and in stained films (Friess et al. 1953)

Histopathology

All tissues were fixed in 10% formalin or Zenker's solution. Complete transverse sections of the two lungs about 0 5 cm thick were cut, divided into portions of a convenient size, and after processing embedded in paraffin-wax blocks The lung, liver, and lymph-node biopsy material was divided if necessary and similarly embedded. All of these blocks were sectioned completely at 7 μ. The sections were stained with hæmatoxylin and eosin, and all of each section was searched under the high-power lens (magnification × 450)

Results

LUNG CASES

Case 1 —A man, aged 28, was admitted on Dec. 1, 1950 Three months previously he had developed fever and pain in the chest, followed by persistent cough. He was of poor physique, weighing 88 lb There was slight impairment of percussion note over the left upper lobe anteriorly, but no adventitious sounds in either lung Hæmoglobin was 10 75 g per 100 ml, total leucocytes 22,700 per c.mm. (neutrophils 56%, eosinophils 36%, and lymphocytes 8%) and erythrocyte-sedimentation rate (E.S.R.) 4 and 25 mm. after the first and second hours (Westergren) A chest radiograph showed a dense opacity in the upper zone of the left lung with apparent cavitation At bronchoscopy the left-upper-lobe bronchi were patent and a bronchogram showed dye entering the lesion. With a provisional diagnosis of lung abscess, left upper lobectomy was performed on Dec 15 Cough persisted postoperatively, and on Jan 8, 1951, eosinophils were 63% of a total leucocyte-count of 20,800 per c.mm. This high eosinophilia and the massive eosinophil infiltration found on histological examination of the resected specimen suggested a diagnosis of tropical eosinophilia

A course of arsenic injections relieved his symptoms completely for eleven months when cough and eosinophilia (white blood-cells 17,000 per c.mm , eosinophils 53%) were found to have recurred

Case 2 —A man, aged 22, was admitted on Sept 11, 1957, with a two-year history of cough and breathlessness The cough had varied in severity from time to time, had occasionally been accompanied by wheezing and had been productive of up to 10 oz a day of watery inoffensive sputum which had never been bloodstained Breathlessness had been severe, ultimately limiting his walking to about one furlong, and present even at rest

He was a man of poor general physique, weighing 98 lb , dyspnœic at rest though not cyanosed There was evidence of displacement of the mediastinum to the right, with rhonchi and a few medium crepitations throughout the right lung and at the base of the left lung, and a hyperresonant percussion note with much-diminished breath sounds over the front and most of the back of the left chest Hæmoglobin was 11 75 g per 100 ml , total leucocytes 17,500 per c mm (neutrophils 26%, eosinophils 62%, and lymphocytes 12%), the E S R was 120 and 130 mm in the first and second hours (Westergren), the absolute eosinophil-count one week later was 5200 per c mm F C F T was positive at 1 in 40 One blood specimen was negative for microfilariæ Urine was normal, two stools contained hookworm ova Two specimens of sputum were negative for tubercle bacilli Posteroanterior and lateral chest radiographs showed a huge tension cyst occupying most of the left chest, extending across the mediastinum and displacing it to the right, there were also increased reticular markings in the right lung

On Sept 19, left pneumonectomy was performed, the postoperative course was uneventful The patient was then treated with diethylcarbamazine 200 mg three times daily for one week. After a further week his eosinophil-count was 330 per c.mm and after two weeks 900 per c mm and the F C F T positive at only 1 in 10 At this time he was free from all symptoms

Case 3 —A boy, aged 11 years, was admitted on Aug 19, 1959, with a three-month history of cough, occasional wheezing, and breathlessness, all symptoms being worse at night He was of average physique (weight 43 lb), cheerful and active There were rhonchi and medium crepitations throughout both lungs There was no significant lymphadenopathy, the liver was palpable 1 cm below the costal margin in the mid-clavicular line and normal in consistence, the spleen was not palpable

Hæmoglobin was 10 5 g per 100 ml , total leucocytes 25,000 per c.mm (neutrophils 30%, eosinophils 44%, basophils 1%, lymphocytes 24%, and monocytes 1%), and absolute eosinophil-count was 9800 per c.mm , E S R. 30 and 69 mm in the first and second hours (Westergren), F C.F T positive at 1 in 640 Intradermal purified-protein derivative (P P D) was negative with 50 tuberculin units (T U) A chest radiograph showed coarse soft mottling throughout both lung fields In three stools *Entamœba coli* cysts were the only abnormal finding Six night specimens of blood were negative for microfilariæ, including three by the Knott (1939) concentration technique after prednisolone, 40 mg daily, had been given for three days

On Aug 24 lung biopsy was performed, and on Sept. 1 a five-day course of diethylcarbamazine 100 mg b d was started He was free of cough by Sept 6, but rhonchi were still present in the lungs three days later when the eosinophil-count was 2880 per c mm On Sept 16, his lungs were clear, eosinophils 1540 per c.mm and F C.F T positive at 1 in 160, and on Nov 13 he was still symptom-free with clear lungs, eosinophils 1200 per c.mm and F C.F T 1 in 160

Case 4 —A boy aged 6 years, was admitted on July 11, 1959, with a history of breathlessness from birth and some deformity of the chest-wall, and cough intermittently for three or four years He was thin and small for his age (weight 32 lb) with a prominent precordial bulge His heart was enlarged with a continuous murmur at the base characteristic of patent ductus arteriosus (P D.A) There were medium crepitations in both lungs There was no significant lymphadenopathy, the liver was not enlarged, but the spleen was palpable 2½ in below the costal margin.

Hæmoglobin was 13 25 g per 100 ml , total leucocytes 46,000 per c.mm (neutrophils 4%, eosinophils 77%, and lymphocytes 19%), E S R 40 and 85 mm in the first and second hours (Westergren) Five night specimens of blood were negative for microfilariæ by Knott's concentration technique F C F T was positive at 1 in >1280 Chest radiographs and fluoroscopy showed enlargement of both ventricles of the heart and of the pulmonary conus, and increased pulmonary vascular markings, with coarse mottling throughout both lung fields

Cardiac catheterisation confirmed the diagnosis of patent ductus arteriosus, and on Aug 25, after prednisolone had cleared the lungs of moist sounds, the ductus was ligated, lung tissue being taken at the same time for biopsy The patient made an uneventful recovery from the operation, and on Sept 13 a five-day course of diethylcarbamazine, 50 mg t i d , was started On Oct 22 he was symptom-free with clear lungs, and eosinophils had fallen to 2100 per c mm F C.F T was still positive at 1 in >1280

Pathology

The lung tissue, before fixation, felt soft and spongy, but nodules were readily palpable The cut surface showed irregularly scattered whitish nodules 3–5 mm in diameter, the distance between nodules varying from 1 to 3 cm In one segment of one lung (case 1) there was a larger area of consolidation in which the nodules were closer together

Microscopic examination of these lungs showed that the architecture was well preserved There was slight œdema of alveolar walls in most areas In the vicinity of the nodules there was infiltration of the alveolar walls by eosinophils, and septal cells were protruding into many of the alveoli, some of which contained collections of macrophages

Nodules were scattered irregularly through the lung, without any particular relation to bronchi or blood-vessels Some nodules were formed by areas of consolidation involving 20–30 alveoli which were distended with eosinophils enmeshed in fibrin In the centre of some of these nodules, alveolar walls were destroyed with the formation of an eosinophil abscess (fig 1), and in the centre of some of these abscesses portions of microfilariæ were found (fig 3)

In other nodules the central collection of eosinophils was replaced by epithelioid cells, which were sometimes arranged like a palisade round deeply acidophilic hyaline

Fig 1—Lung section showing area of eosinophil aggregates. (H & E. ×400)

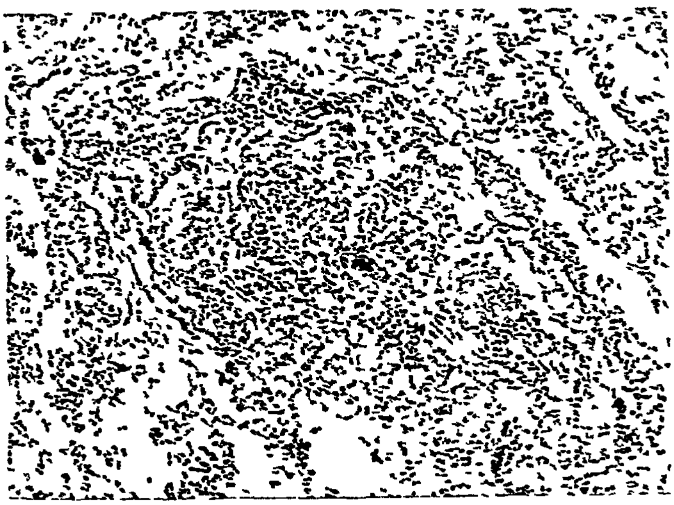

Fig 2—Lung section showing nodule with granuloma at the centre composed of epithelioid cells surrounding an M.K. body, and surrounding tissue infiltrated with many eosinophils. (H. & E. ×90.)

material (fig 2). In some instances this hyaline material contained fragments of degenerating larvæ.

Other nodules showed some fibrosis at the periphery. In these, eosinophils were less evident, and at the centre there were epithelioid and giant cells surrounding amorphous hyaline material (figs 4 and 5). In such nodules no fragments of parasite could be identified.

Parasites

In some 5000 sections examined, five almost complete microfilariæ were found—one in case 1, three in case 2, and one in case 3. Slides containing two of these microfilariæ were sent to Prof. P. C. Beaver (professor of parasitology, University of Tulane, New Orleans, La, U.S.A.), who reported on one which ran through three sections as follows:

"The objects on the slides are indeed portions of a microfilaria. They are serial sections and the three together contain almost all the microfilaria. It is almost certain that only one section is lacking and it contained a small portion of the anterior end and a short segment in the third quarter of the body. The reconstructed portions constitute a length between 200 and 230 microns and the greatest width is approximately 7 microns. There appears to be no question about it having been dead for a brief period before it was fixed."

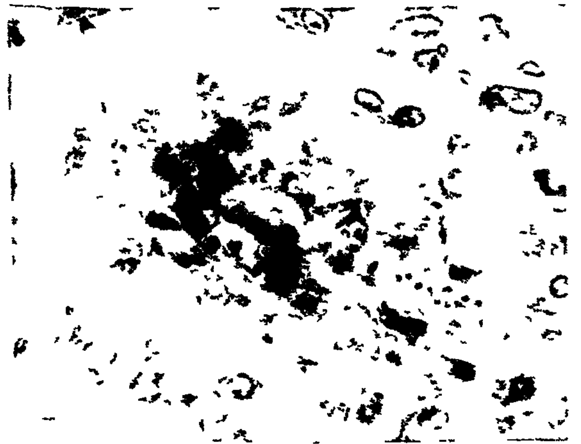

Fig 3—Lung section showing portion of microfilaria surrounded by eosinophilic material, collections of epithelioid cells at periphery, and fine black dots in body of microfilaria. (H. & E. ×1000.)

The other microfilariæ were essentially similar in appearance.

In addition, recognisable fragments of microfilariæ were found in seventeen different nodules. Some of these fragments were found in eosinophil aggregates. Others were in the centre of acidophilic hyaline material, their appearance being suggestive of that described by Meyers and Kouwenaar (1939) and sometimes referred to as Meyers-Kouwenaar (M.K.) bodies.

LIVER CASES

Case 5.—A girl, aged $4^1/_2$ years, was admitted on Aug. 18, 1958. Her early development had been normal; there was no previous history of significant illness. In the month before admission her parents had noticed her wheezing during sleep, and for three weeks she had been coughing. Her appetite had been poor, but there had been no fever and no obvious reduction of activity.

She was a small undernourished child, weighing $25^1/_2$ lb. Xerophthalmia was present. There were rhonchi and medium crepitations throughout both lungs. The liver was palpable 2·5 cm. below the costal margin in the midclavicular line, was painless, and felt normal in consistence. The spleen was not palpable. There was no significant lymphadenopathy. Her hæmoglobin was 12·9 g. per 100 ml., total leucocyte-count 28,200 per c.mm. (neutrophils 18%, eosinophils 65%, and lymphocytes 17%), the E.S.R. was 17 and 31 mm. in the first and second hours. No malarial parasites were seen in a blood-film, and one night specimen of blood was negative for microfilariæ. Urine was normal, and two stools were negative for cysts and ova. An intradermal tuberculin test with 5 T.U. of P.P.D. was negative. F.C.F.T. was positive at 1 in 160. A chest radiograph showed extensive soft miliary mottling throughout both lung fields (fig. 9*a*).

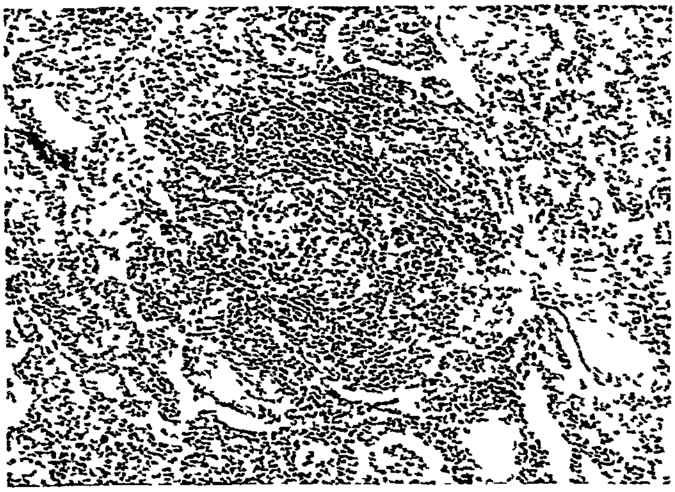

Fig 4—Lung section showing nodule with giant cells and epithelioid cells in middle surrounded by eosinophils. (H. & E. ×90.)

At laparotomy on Aug. 27, the liver was slightly enlarged and normal in general appearance and consistence, but scattered over the anterosuperior surface were 20–30 whitish spots varying from 1–3 mm. in diameter. A piece of tissue including some of these spots was taken for biopsy from the anterior aspect of the left lobe. Recovery from operation was uneventful. The patient was referred to a special clinic for inclusion in a controlled therapeutic trial, but she failed to attend. Contact with her was lost for one year.

SUMMARY OF CLINICAL AND PATHOLOGICAL FEATURES OF CASES

Case no	Sex	Age (yr)	Presenting symptoms	Lymph-adenopathy	Hepato-megaly	Lung signs	X-ray evidence of pulmonary infiltration	Typical pathological lesions demonstrated in	Evidence of microfilariæ in	F C.F T (dilution)	Thera peutic response
1	M	28	Cough	0	0	+	+	Lung	Lung		–
2	M	22	Cough and breathlessness	0	0	+	+	Lung	Lung	40	+
3	M	11	Cough, wheeze, and breathlessness	0	?+	+	+	Lung	Lung	640	+
4	M	6	Cough and breathlessness (partly due to P.D A)	0	0	+	+	Lung	M K bodies in lung	>1280	+
5	F	4½	Cough and wheeze	0	+	+	+	Liver	Liver	160	+

7	M	7	Cough and wheezing	+	0	+	+	Lymph-node	Lymph-node	320	+
8	F	2½	Enlarged lymph-nodes	+	+	0	0	Lymph node	Lymph node	80	+
9	M	7	Enlarged lymph-nodes	+	+	0	0	Liver and lymph-node	Lymph-node	20	?
10	M	6	Cough	+	+	+	+	Lymph-node	Lymph-node	2560	+

On Sept 1, 1959, she was seen again Symptoms had subsided gradually after the laparotomy, and she had been regarded by her parents as healthy for the previous nine months Her lungs were clear, and her liver was no longer enlarged An absolute eosinophil-count was 2820 per c.mm, and F C.F T still positive at 1 in 160 A chest radiograph showed that the mottling had cleared, but there were still increased linear striations in both lungs She was treated with diethylcarbamazine 50 mg three times daily On Nov 18 she was symptom-free and had gained weight the chest radiograph showed further clearing (fig 9b), eosinophils were 1370 per c.mm, and the F C.F T was positive at 1 in 80

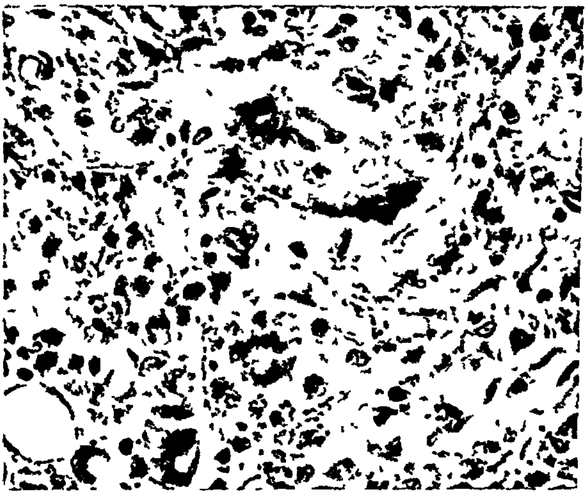

Fig 5—Centre of nodule in fig 4 showing eosinophilic hyaline material at centre surrounded by many giant cells, epithelioid cells, and occasional eosinophils (H & E ×520)

Case 6 —A boy, aged 7 years, was admitted on Aug 10, 1959, with a rather vague history of ill health for the previous year Symptoms included anorexia, occasional epistaxis, bouts of fever and cough, and some weight loss He was a cheerful child, not ill-looking, and of average physique (weight 42 lb) There was no significant lymphadenopathy, the lungs were clear, the liver was enlarged 3 5 cm below the costal margin in the midclavicular line and 5 0 cm in the midline, and slightly firmer than normal in consistence, and the spleen was palpable 5 cm. below the costal margin

Hæmoglobin was 10 0 g per 100 ml , total leucocytes 38,500 per c.mm (neutrophils 10%, eosinophils 77%, and lymphocytes 13%), total eosinophils 28,645 per c.mm Four night specimens of blood were negative for microfilariæ. F C.F T was positive at 1 in 640 Total serum-protein was 8 2 g per 100 ml , icteric index 4 units, thymol turbidity 2 units, thymol flocculation ++, and zinc-sulphate turbidity 6 units Platelets were 310,000 per c mm , and bleeding, clotting, and prothrombin times normal The bone-marrow was normoblastic, with no abnormality apart from the eosinophilia A chest radiograph showed faint reticular markings in both lungs of very doubtful significance, a barium swallow showed no evidence of œsophageal varices

At laparotomy on Aug 24, the liver was considerably enlarged and densely studded with white spots about 2 mm in diameter, the spleen was enlarged to about three times the normal size, felt firm in consistence, and showed a pronounced perisplenitis Tissue was taken from the liver for biopsy, but none from the spleen. On Sept 1 a five-day course of diethylcarbamazine 100 mg b d was started On Nov 4 the liver was palpable 2 5 cm below the costal margin, and the eosinophils were 12,130 per c mm A second five-day course of diethylcarbamazine, 200 mg b d , was given On Nov 14 the liver had receded further to 1 5 cm in the midclavicular line, and the eosinophils were 4200 per c mm. On Nov 25 the eosinophils had dropped to 1570 per c mm and the F C.F T was positive at 1 in 640

Pathology

In addition to these two cases (5 and 6) and case 9, reported below, liver tissue was obtained by open biopsy from a further four children, with typical tropical (pulmonary) eosinophilia In these seven children the surface of the liver was found at laparotomy to be studded with whitish dots 2–5 mm in diameter In some there were

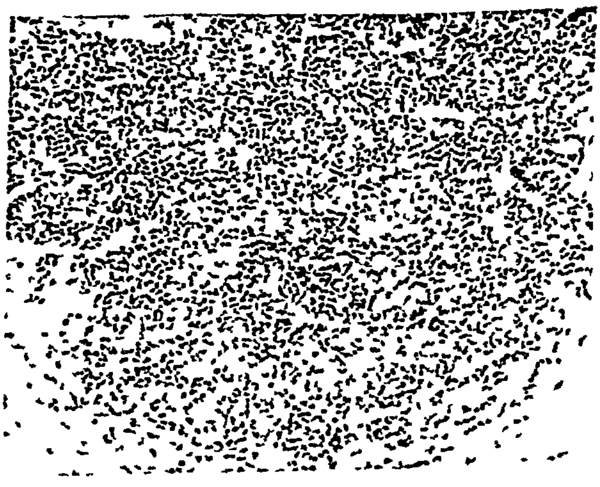

Fig 6—Liver nodule consisting of eosinophils and a few histiocytes replacing liver tissue (H & E ×118)

only 4–5 of these dots, in others 20–30, and in one (case 6) there were hundreds.

On microscopic examination the normal lobular pattern of the liver was preserved. The cells were well glycogenated, and there was no evidence of fatty change or congestion. There was patchy infiltration by eosinophils round portal tracts, in some instances this infiltration was slight, in others very extensive. In addition nodules were scattered through the liver parenchyma in each of the seven livers examined. These nodules bore no constant relation to the lobular pattern. The structure of these nodules was essentially similar to that of those seen in the lungs, varying from lakes of eosinophils to mature granulomata containing giant and epithelioid cells (figs 6 and 8).

Parasites

In some 3000 sections examined, one almost complete microfilaria was found in the centre of an aggregate of eosinophils (case 5). The organism ran, in all, through nine serial sections. In seven of the sections the cuts through the parasite were either transverse or only slightly oblique. These sections included a portion of the microfilaria measuring 60–70 µ in length. In three of these transverse sections the organism was encased in a collar of acidophilic hyaline material. In the eighth section a curved and thinned-out portion approximately 20 µ in length could be seen and, separated from this by a distance of 40 µ, another piece of the organism 10 µ in length which was probably one end. The ninth section included the greatest length of the organism—about 85 µ (fig 7). The total length included in these sections was at least 160 µ, the greatest width 6–7 µ. Although in some portions the details were indistinct, in others the outline of the body and the contained nuclei were readily apparent.

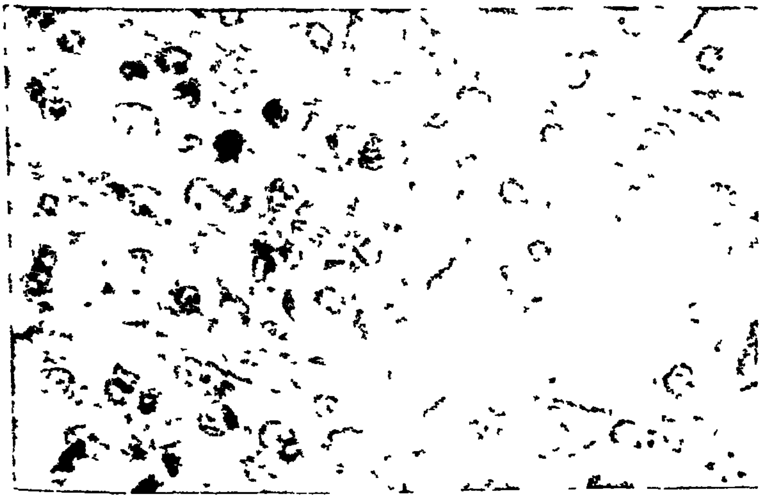

Fig 7—Liver showing microfilaria in middle of eosinophilic aggregate, and the long larva with dots in its body crossing the field. (H & E. ×1000)

These sections have been seen by Professor Beaver, who confirmed that the organism was a microfilaria

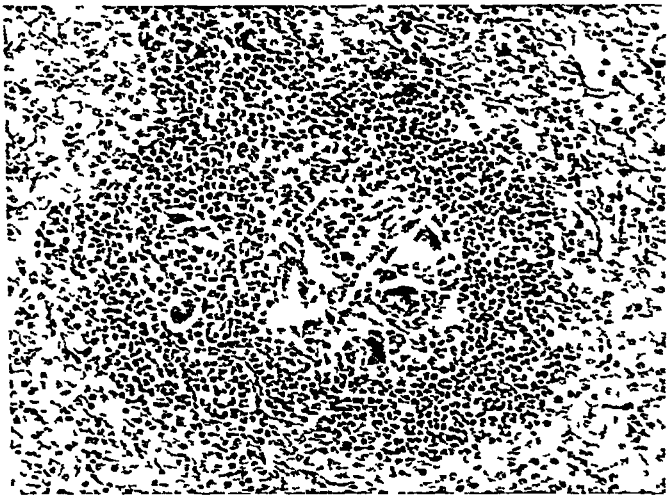

Fig 8—Liver showing granuloma consisting of giant cells in middle surrounded by epithelioid cells and many eosinophils (H. & E. ×130)

In two other livers, lesions suggestive of M K bodies were seen, but no recognisable portions of parasite were found.

LYMPH-NODE CASES

Case 7—A boy, aged 7 years, was admitted on Aug 29, 1959, with a six-month history of cough and wheezing. Cough had first developed during a five-day febrile illness, but persisted after subsidence of the fever; both cough and the tendency to wheeze had been worse at night. His general nutrition was fair (weight 40 lb). There were rhonchi throughout both lungs. The liver was just palpable at the costal margin, the spleen could not be felt. The axillary and inguinal lymph-nodes were moderately enlarged, the largest being in the left axilla and measuring 2·0 cm in diameter; they were firm, mobile, and painless.

Hæmoglobin was 11·9 g per 100 ml, total leucocytes 29,400 per c.mm (neutrophils 16%, eosinophils 59%, and lymphocytes 25%), absolute eosinophil-count 17,200 per c.mm. Six night specimens of blood were negative for microfilariæ, including three by the Knott concentration technique. F.C.F.T. was positive at 1 in 320. Intradermal P.P.D. was negative with 5 T.U. A chest radiograph showed dense mottling and strikingly increased reticular markings throughout both lung fields (fig 10*a*).

On Sept. 3 the largest node in the left axilla was removed for biopsy, and on Sept. 10 a five-day course of diethylcarbamazine, 100 mg b.d., was started. Symptoms were

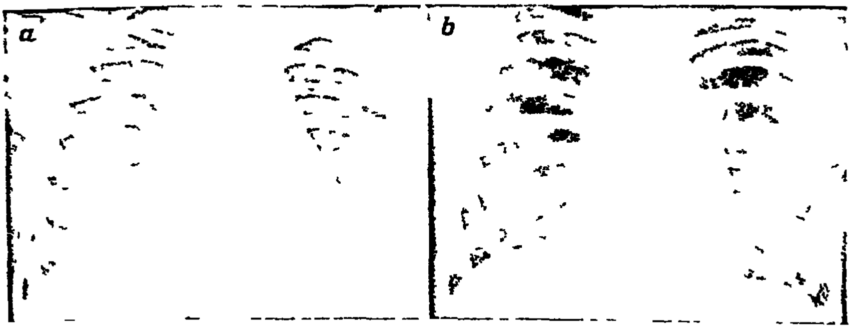

Fig 9—Chest radiographs of case 5 *a*, before treatment *b*, after treatment.

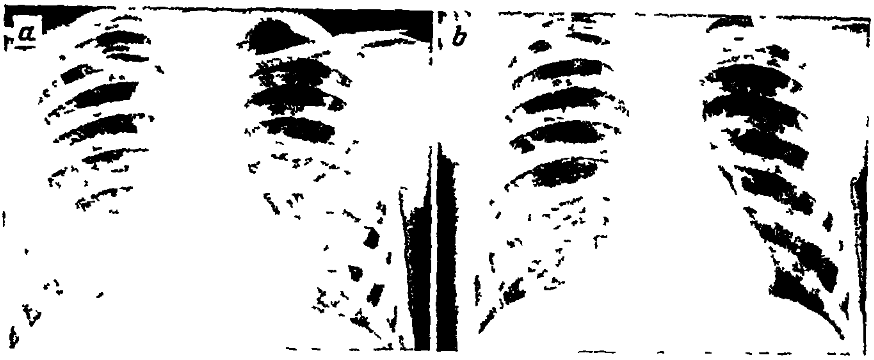

Fig 10—Chest radiographs of case 7 *a*, before treatment, *b*, after treatment

relieved almost immediately, and the absolute eosinophil-count was 5300 per c.mm on Sept 20 and 1706 per c mm on Sept 29 On Nov 3 the patient was symptom-free, the eosinophil-count was 1980 per c mm , and the F C F T was positive at 1 in 320 On Nov 25 he was still symptom-free, eosinophils were 1560 per c.mm , and the F C F T titre had fallen to 1 in 80

Case 8 —A girl, aged 2½ years, was seen on April 14, 1959 Her father, who was a doctor, had found two days previously a moderate generalised enlargement of lymph-nodes, but apart from this finding she had no symptoms She was a small active child (weight 23 lb) Lymph-nodes in all groups were slightly enlarged, mobile, and painless the largest were in the right axilla and measured 2 5 cm in diameter The lungs were clear The liver was palpable 4 cm below the costal margin in the midclavicular line and 5 cm in the midline, and felt slightly firmer than normal in consistence, the spleen was palpable 2 cm below the costal margin

Hæmoglobin was 8 0 g per 100 ml , and total leucocytes were 22,000 per c mm (neutrophils 26%, eosinophils 50%, lymphocytes 20%, and monocytes 4%), an absolute eosinophil-count 14,000 per c.mm Three night specimens of blood were negative for microfilariæ by the Knott concentration technique—one after twenty-four hours of prednisolone F C F T was positive at 1 in 80 A chest radiograph was normal

Lymph-node biopsy was performed on April 15, and on April 19 a five-day course of diethylcarbamazine, 125 mg daily, was started. On April 27 an absolute eosinophil-count was 5300 per c mm The patient was then not seen again until Aug 11 when the hepatosplenomegaly had subsided, an eosinophil-count was 940 per c mm , and the F C F T was positive at 1 in 10

Case 9 —A boy, aged 7 years, was admitted on April 20, 1959, on account of a swelling which had been present in the right axilla for three months During this period he had had two brief episodes of fever, cough, and wheezing, but apart from these had remained well He was of fair general nutrition and physique, weighing 32 lb There was generalised modest lymphadenopathy, nodes measuring 1–1 5 cm. in diameter, except in the right axilla where one was 3 0 cm , all nodes were firm, mobile, and painless The liver was palpable 2 5 cm below the costal margin in both the midclavicular line and the midline The lungs were clear

Hæmoglobin was 11 5 g per 100 ml. and total leucocytes 17,100 per c.mm. (neutrophils 25%, metamyelocytes 1%, eosinophils 59%, lymphocytes 13%, and monocytes 2%), absolute eosinophil-count 9200 per c.mm Ten specimens of blood were negative for microfilariæ—seven of these by the Knott concentration technique, four after a five-day course of prednisolone, 30 mg daily F C.F T was positive at 1 in 20 A stool contained giardia cysts A chest radiograph was normal

On April 22 a lymph-node was removed, and on May 2 laparotomy was performed. The liver was slightly enlarged with white dots scattered over the surface, tissue was taken for biopsy On May 12 a five-day course of diethylcarbamazine, 50 mg t i d , was started. Unfortunately, contact with this child was then lost

Case 10 —A boy, aged 6 years, was admitted on May 4, 1959, with a two-year history of cough, productive during the previous month, and occasional fever and wheezing He was of average physique and nutrition (weight 36½ lb) There was a group of enlarged lymph-nodes in the right axilla, these were firm, mobile, and painless, the largest measuring 2 5×3 5 cm Nodes in other groups were palpable but not significantly enlarged The lungs were clear, the liver was palpable 2 cm below the costal margin in the midclavicular line, and normal in consistence, the spleen was palpable 1 5 cm. below the costal margin

Hæmoglobin was 10 25 g per 100 ml , total leucocytes 27,000 per c mm (neutrophils 17%, eosinophils 68%, and lymphocytes 15%), absolute eosinophil-count 14,650 per c.mm Eight night specimens of blood and 1 day specimen of blood were negative for microfilariæ by the Knott concentration technique—four of them after a four-day course of prednisolone, 40 mg daily F C F T was positive at 1 in 2560 A chest radiograph showed coarse reticular markings in the upper zone of the right lung suggestive of cystic bronchiectasis but no diffuse changes characteristic of tropical eosinophilia A stool was negative for cysts and ova

On May 9 lymph-node biopsy was performed On recovery the patient was taken home unexpectedly before receiving diethylcarbamazine He was seen again on June 12, when he was symptom-free with an eosinophil-count of 16,400 per c.mm He returned on Aug 21, moderately ill, with productive cough and fever and signs suggesting pneumonia in the bronchiectatic right lung This responded to penicillin and sulphadimidine On Aug 26, although no specific therapy had been given, an absolute eosinophil-count was 40 per c.mm , the F C F T was still positive at 1 in 640 He was not seen again until Nov 13, when he still had cough and scattered rhonchi in both lungs with eosinophils 4200 per c mm. and F C.F T positive at 1 in 2560 He was treated with diethylcarbamazine 100 mg b d. for five days On Dec 2 he was remarkably improved with no cough, clear lungs, and eosinophils 2100 per c mm (The low eosinophil-count on Aug 25 was probably due to the stress of an intercurrent infection We have observed similar falls in eosinophil-counts after surgical operations)

Pathology

The lymph-nodes from these four cases were soft and fleshy in consistence Their greatest diameters varied from 2 0 to 3 5 mm The cut surfaces showed circumscribed areas, brownish or greyish-white and about 1 mm in diameter, scattered irregularly through the node

The microscopic appearances were similar in each of the nodes The architecture was largely preserved Germinal follicles were prominent, and there was a diffuse increase of vascularity with endothelial proliferation The most striking abnormality was in the medullary cords and lymph sinuses, where there were numerous large aggregates of eosinophils These aggregates varied considerably in size They were much less frequently seen in the cortex, though a few were present in the subcapsular region In the centre of some of these aggregates in each node, portions of microfilariæ were seen The capsules of the nodes were thickened and infiltrated with many eosinophils and lymphocytes

Parasites

Wet-drop preparations of the centrifuged deposits of nodes teased in saline were positive for live microfilariæ in cases 7, 8, and 10 In stained films the microfilariæ were sheathed, measured about 300 μ in length, and in each case showed the anatomical features characteristic of *Wuchereria bancrofti* Stained films from case 8 were sent to Professor Beaver, who reported that he found no reason for not calling these *W bancrofti*

In each of the four cases, portions of microfilariæ were found in the centre of some of the eosinophil aggregates In some instances they could be traced through serial sections as complete or almost complete organisms

Discussion

Evidence of Filarial Infection

To the evidence of filarial infection as a cause of tropical eosinophilia previously provided by serology, therapeutic response, and experimental infection of a volunteer, we have now added the demonstration of microfilariæ in the lung The fact that the organisms found were always in the centre of an intense eosinophil or granulomatous reaction leaves no room for doubt about their causal role. Although it is reasonable to assume that all the lung lesions are a reaction to invading microfilariæ, it is important to recognise that almost complete microfilariæ, confidently identifiable as such, were found in only two of the four lungs studied (cases 2 and 3) However, portions of microfilariæ were clearly recognisable in case 1, and case 4 showed typical M K bodies These positive findings need to be viewed against the negative evidence of previous reports on the pathology of the lung in tropical eosinophilia

Viswanathan (1948) found no tissue parasites in the lung he studied, but he made no special search of serial sections, and without this the chances of finding a parasite are extremely slender Our experience is that these organisms are found only after detailed search under the high power of all the serial sections through a large number of lesions Danaraj (1959), on the other hand, did make a detailed search for tissue parasites, but his patient had died from arsenical encephalopathy eight days after starting a course of arsenic, and it seems possible that in this case the arsenic had already killed any organisms present, which had subsequently degenerated beyond recognition

The demonstration of microfilariæ in liver lesions indicates that filarial infection is a possible cause of hepatomegaly with eosinophilia This is a new finding The demonstration of microfilariæ in lymph-nodes confirms that this syndrome of lymphadenopathy with eosinophilia due to some form of filarial infection, previously described in patients from the West Indies (van der Sar and Hartz 1945), Indonesia (Meyers and Kouwenaar 1939), and North Vietnam (Friess et al 1953), also occurs in India The implications of these findings, and their relation to tropical eosinophilia will be discussed in the next section

Clinical Profiles

Tropical eosinophilia most commonly presents as a respiratory disease In fact, the diagnosis will rarely be considered unless respiratory symptoms and clinical and radiological evidence of pulmonary infiltration are present

In a careful study of 123 cases in Malaya, Danaraj (1959) states that hepatosplenomegaly and generalised lymphadenopathy were not evident On the other hand, Ball (1950), working at Vellore, found significant lymphadenopathy in 57 and moderate hepatomegaly in 27 of 100 cases Similarly Baker et al (1959) found enlarged lymph-nodes in 16 5% and slight to moderate enlargement of the liver in 24% of 165 cases, the spleen being palpable in a third of the patients with enlarged livers They noted that in all cases the lymphadenopathy subsided with successful treatment The absence of hepatic and lymph-node involvement in the Malayan cases and the relatively high incidence observed at Vellore can be partly explained by age difference Only 3 6% of Danaraj's cases were under 10 years of age, compared with 43% of Baker's series Ball found a higher incidence of hepatomegaly and lymphadenopathy in children than in adults—45% compared with 16%, and 76% compared with 24%, respectively

The demonstration of eosinophil aggregates or granulomata in all the livers and in one of the lymph-nodes, together with microfilariæ in two instances, in typical cases of tropical (pulmonary) eosinophilia indicates that both liver and lymph-nodes may be involved in this disease Liver involvement has not hitherto been proved, but lymph-node involvement has been suggested by previous workers One at least (case 1) of the cases reported by van der Sar and Hartz (1945) possibly one (case 2) of those reported by Meyers and Kouwenaar (1939), and several of those reported by Friess et al (1953) certainly had sufficient respiratory symptoms and signs to qualify for the diagnosis of tropical (pulmonary) eosinophilia Nevertheless, there has been a tendency in the past, especially in India, to regard cases with significant lymphadenopathy as atypical, and therefore perhaps distinct ætiologically from the common respiratory form of the disease In our opinion this view is no longer tenable One of our cases in which a microfilaria was found in the liver (case 5) and one of those with microfilariæ in the lymph-node (case 7) presented with respiratory symptoms and signs dominating the clinical picture, and both had dense mottling in chest radiographs indicating extensive pulmonary infiltration (figs 9 and 10) These cases are absolutely typical of tropical (pulmonary) eosinophilia, the hepatomegaly and lymphadenopathy were relatively inconspicuous and their true significance was only revealed by biopsy

Our cases 6, 8, 9, and 10, would not normally be regarded as examples of tropical eosinophilia, in that they showed no evidence of lung involvement They are distinguishable, however, only on this basis The massive eosinophilia, the histopathological lesions, the presence of microfilariæ in all except one (case 6), the positive F.C.F T, and the response to diethylcarbamazine are all identical with the lung cases Moreover, the lung cases included examples of lesions apparently confined to the lung, of lesions of lung and liver combined, and of lung and lymph-node lesions combined Among the cases with no lung involvement were examples of isolated lymphadenopathy, of combined lymph-node and liver involvement, and of isolated liver lesions possibly combined with splenic lesions but certainly without lung or lymph-node involvement To separate these cases into distinct disease entities appears to us unreasonable

All the cases reported here have a common ætiology—namely, infection with some form of filaria Possibly different filariæ are involved, and particular clinical profiles are associated with different species Until this has been proved, however, it seems reasonable to enlarge the concept of tropical eosinophilia to embrace the non-pulmonary forms of the disease, and to use the descriptive qualifications pulmonary, hepatic, and lymphatic when necessary On the other hand it seems desirable to reserve the diagnosis of tropical eosinophilia for those cases where a filarial infection is suspected or proved Similar syndromes are certainly caused by other parasites—e g, *Toxocara canis* (Beaver et al 1952, Chaudhuri and Saha 1959)—but probably the F C F T will serve to differentiate these

Pathogenesis

It now seems clear that tropical eosinophilia in all its possible clinical manifestations is usually due to infection with some form of filaria The demonstration of microfilariæ in lesions in lung, liver, and lymph-nodes implies at least two things First, infective larvæ introduced by mosquito-bite must have developed somewhere in the body into sexually mature adult filariæ capable of producing microfilariæ The intervals of fourteen and ten weeks in Buckley's (1958) experiments between the injection of infective larvæ and the development of cough and eosinophilia is consistent with this idea (Edeson and Wharton 1957) Secondly, the lesions in all the tissues involved in tropical eosinophilia appear more likely to be due to direct invasion by microfilariæ than to be the result of visceral allergy provoked by some remotely situated organism

It seems reasonable to suppose that during the active phase of the disease microfilariæ continue to be liberated from the adult worms only to become trapped in the tissues, dying there and exciting the characteristic eosinophilic reaction Fragments of disintegrating microfilariæ must continue to excite a vigorous reaction long after the disappearance of anything recognisable histologically as part of an organism This would partly explain the relatively small proportion of nodules which are found to contain organisms The duration of symptoms must depend on the survival-time of the adult filariæ, though reinfection is clearly possible at any time It seems difficult to explain the wide dissemination of lesions in tropical eosinophilia except on the basis of hæmatogenous spread of the microfilariæ This must be reconciled with the consistent absence of microfilaræmia, even after prednisolone The explanation may be that the microfilariæ after release into the blood-stream are trapped in the first set of capillaries through which they pass This will normally be in the lung, which would account for the predominance of pulmonary involvement in this disease The alternative hypothesis that dissemination is confined to the lymphatic system is difficult to accept

The particular tissue response to microfilariæ characteristic of tropical eosinophilia is almost certainly related to the species of filaria involved Buckley's (1958) experiments have provided the strongest possible evidence that this filaria is of animal origin Unfortunately, in none of the cases reported in this paper has a specifically identifiable microfilaria been found in viscera It is reasonable, however, to assume that in case 7 similar microfilariæ to those found in the lymph-node were responsible for the lung lesions These microfilariæ are morphologically indistinguishable from those of *W bancrofti* This finding does not, however, rule out the possibility that they are of animal origin Edeson et al (1955) reported the recovery of sheathed microfilariæ indistinguishable from *W malayi* from five different species of animal in Malaya Further observations on the life-cycles of these microfilariæ revealed that at least two species of filaria were involved On the strength of this evidence Buckley (1958) has pointed out that the identification as *W malayi* of microfilariæ found in gland biopsies by the Dutch and French workers is open to doubt Similarly, the microfilariæ found in the cases reported here may be bancrofti-type microfilariæ of animal origin, but this at the moment is speculation

Summary

The pathological changes in the lung, liver, and lymph nodes of typical cases of tropical pulmonary eosinophilia are described

Microfilariæ have been demonstrated in the centre of nodules in each of these tissues, suggesting that direct invasion by these organisms is the cause of the lesion in this disease

Cases are reported with lymph-node and hepatic, but without lung, involvement The lesions in these cases were similar to those seen in the lung, and microfilariæ were present A plea is made to enlarge the concept of tropical eosinophilia to include such cases, and at the same time to restrict the diagnosis to those in which a filarial infection is proved or suspected

Microfilariæ recovered from lymph-nodes have been provisionally identified as *W bancrofti*-type, but, on the analogy of findings in Malaya, these may be of animal origin, and zoonotic filariasis remains the most likely explanation of tropical eosinophilia

It is a pleasure to acknowledge the many ways in which Prof P C Beaver has helped and encouraged us, in particular we are grateful to him for the photomicrographs of the lung and liver sections, and for the supplies of *Dirofilaria immitis* antigen used in the F C F T We are grateful to many colleagues, both surgical and medical—particularly to Dr R H Betts, head of the thoracic unit, who performed all the thoracotomies, to Dr S J Baker, associate professor of medicine, for case 2, to Dr Ruth M Myers, professor of microbiology for carrying out the F C F TS, and to junior colleagues in the pædiatric department for their recognition and care of many of the cases We are also most grateful to Messrs Burroughs, Wellcome for a grant which covered some aspects of this study

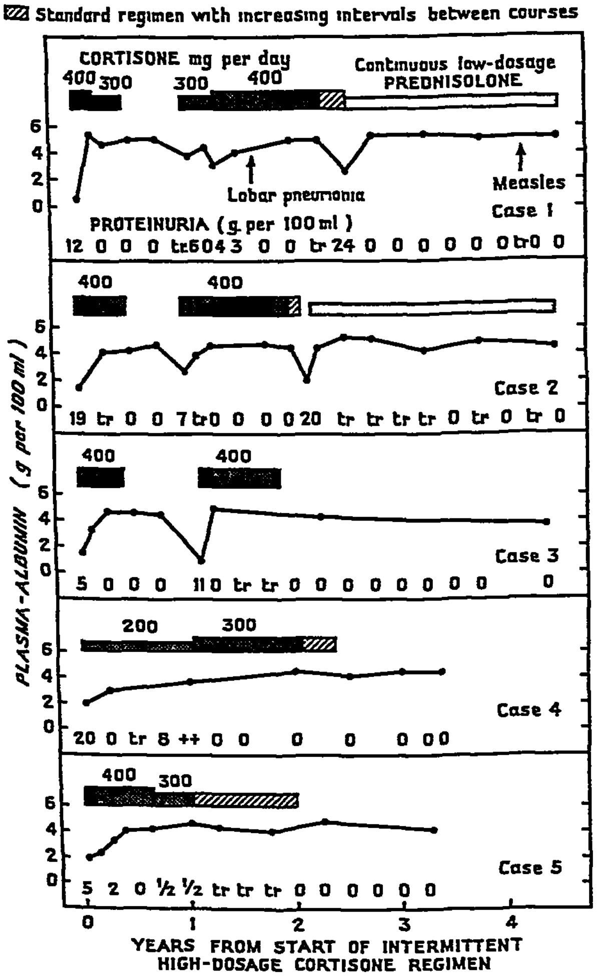
" Suppose that a conspiracy of unusually public-spirited scientists were to study all the accidental deaths in the world, famine, traffic, and disease included, and by an effort of international cooperation could fabricate evidence that these accidents were really the work of a malicious adversary—say the Martians, the devil is too long dead Suppose they successfully kidded and frightened their governments—exactly as they have to do now when a constructive proposal needs to be got through They would find that the protein deficiencies in Africa were part of an organised strategy of conquest, and protein deficiency would be gone in one year, not ten "—Dr ALEX COMFORT, *Listener*, March 24, 1960, p 517

THE NEPHROTIC SYNDROME
TREATED WITH CORTISONE IN INTERMITTENT HIGH DOSAGE

R G MITCHELL
M D Edin, F R C P E, D C H
PÆDIATRICIAN, DUNDEE ROYAL INFIRMARY,
LECTURER, DEPARTMENT OF CHILD HEALTH, UNIVERSITY OF ST ANDREWS

ALTHOUGH steroid therapy represents a great advance in the symptomatic treatment of the nephrotic syndrome in childhood, its influence on the outcome of the disease is still uncertain (Burke 1958, Kohn 1958) In 1951, Lange and his colleagues in New York introduced a regimen involving very large doses of cortisone given intermittently over long periods, and cited experimental evidence that such a scheme might inhibit the nephrotic process long enough to effect a permanent cure (Lange et al 1953, 1955) In the past few years others, in the United States and France, have advocated this type of treatment (Piel and Williams 1957, Debré et al 1956), but in this country continuous low-dosage therapy has been favoured (Arneil 1958) Recently, however, it has been suggested that intermittent high dosage with steroids might be the treatment of choice (*Lancet* 1958), and an account of its use in a small group of children is therefore of interest



Steroid therapy, plasma-albumin levels, and urinary protein in five cases of nephrotic syndrome

Because more than a third of all children with nephrosis recover either spontaneously or after a single course of hormone treatment (Mateer et al 1957, Vernier et al 1958), a very large number of previously untreated cases would be required to establish the superiority of a high-dosage steroid regimen over continuous low-dosage therapy But if one could show that a high-dosage regimen consistently cured nephrosis which had not responded to other treatment schemes, or had remitted and later relapsed, fewer cases might suffice to establish its greater efficacy Accordingly, in 1955, the Lange treatment was introduced for all children with nephrosis, attending the Dundee Royal Infirmary, who had failed to respond to one or more courses of hormone therapy or who had relapsed after a temporary remission This report is based on experience with five such children who started the regimen between April, 1955, and July, 1956, and whose progress has been followed for at least 3 years

The Study

The terms "nephrotic syndrome" and "nephrosis" are here used to indicate a syndrome of unknown ætiology characterised by œdema, proteinuria, hypoalbuminæmia, and hypercholesterolæmia. No attempt has been made to distinguish between lipoid nephrosis and nephrotic nephritis (Arneil 1958) In assessment even a trace of protein in the urine was regarded as a sign that the nephrotic process might still be active

The Patients

All the children were girls, and all had severe œdema, hypoalbuminæmia and proteinuria when the Lange treatment was begun (see figure) Their ages ranged from $4^{1}/_{2}$ to $12^{3}/_{4}$ years, and the nephrotic syndrome had lasted from 9 months to 3 years All the children had had hormone treatment, either unsuccessfully or with subsequent relapse (see table for details)

The Regimen

At the start of the intermittent high-dosage regimen, corticotrophin was given intramuscularly in a dose of 20 mg twice daily for 14 days Although this dose is smaller than that recommended by Lange (Lange et al. 1957), it resulted in satisfactory diuresis and disappearance of œdema in all except one child (case 5) whose œdema did not disappear completely until the 2nd week of maintenance therapy

5 days after the course of corticotrophin was completed, treatment with cortisone acetate was begun, 100 mg was given by mouth every 6 hours for 3 consecutive days, the total dose thus being 1200 mg. After 4 days without hormone treatment, this 3-day course was repeated. The regimen of 3 days' treatment in each week was then continued until the recommended number of courses had been given. When this treatment was first used in cases 1–3, cortisone was stopped abruptly after 20 weeks, a period chosen because Lange et al. (1955) had reported that shorter periods did not prevent relapses But in the later treatment of these cases, and in cases 4 and 5, the aim was a minimum of 52 weeks' high-dosage therapy, as advised by Lange et al. in 1957 and 1958, followed by gradual lengthening of the interval between the 3-day courses over several months

The corticotrophin was given in hospital, and the children usually went home after 2 weeks' cortisone maintenance therapy Fluid intake was not restricted, and additional potassium was not given except at the time of the initial diuresis After the acute phase the children were encouraged to eat a diet rich in protein and without added salt, but no attempt was made to control their diets more accurately From the beginning of treatment, 1 tablet of penicillin G (200,000 units) was given twice daily as a prophylactic, and this is being continued in all except one child (case 3)

DETAILS OF STEROID TREATMENT IN FIVE CASES OF THE NEPHROTIC SYNDROME

Case no	Age (yr)		Previous treatment		First intermittent high-dosage regimen		Time between end of first series and clinical relapse	Second intermittent high-dosage regimen		Time between end of first series and clinical relapse	Present age (yr)
	At onset of nephrotic syndrome	At start of intermittent high-dosage regimen	Steroid	Total no of days	No of weekly 3-day courses	Total daily dose of cortisone (mg)		No of weekly 3-day courses	Total daily dose of cortisone (mg)		
1	$4\frac{3}{4}$	$5\frac{1}{2}$	Corticotrophin	12	6 16 } 22	400 300	6 mos	16 54 } 70	300 400	3 mos	10

Results

The details of treatment and the further progress of each patient are shown in the figure and table

In case 1 the daily dose of cortisone was reduced from 400 to 300 mg after six 3-day courses because the blood-pressure rose to 140/100 mm Hg and remained at that level, falling to 130/95 only after the dose had been reduced. In her second series of courses the daily dose was 300 mg at first, but it was increased to 400 mg after sixteen courses because of a slight clinical relapse The diastolic pressure remained below 100 mm Hg despite the increase

The first two patients (cases 1 and 2) were free from signs of nephrosis while on the full maintenance regimen, but in both of them, severe proteinuria and moderate œdema recurred within 3 months of starting to reduce the dosage, although each had had a full year of treatment In view of the failure to cure the nephrosis, and the high cost of the regimen, these two girls were afterwards maintained continuously on prednisolone in low dosage, both are now well, although occasional slight proteinuria probably indicates that the nephrotic process is still active

Case 3 relapsed after the first maintenance period of 20 weeks, and during the second period the child left the district But the full maintenance regimen was continued for 36 weeks, and then it was stopped because her blood-pressure was persistently 140/100 and her weight was increasing She had been difficult to manage for a while before cortisone was stopped, but this may have been a side-effect of the treatment as her temperament improved afterwards

Because case 4 was so young, the standard regimen was modified, and cortisone 200 mg was given daily After fifty-two 3-day courses, however, she still had some proteinuria, and for the second series of courses the daily dose was increased to 300 mg without untoward effect This is the dose recommended by Lange et al (1958) for children weighing less than 40 lb , since the child weighed 38 lb at the time, it represents the full maintenance treatment, which was continued for 54 weeks and followed by gradual withdrawal of cortisone over 24 weeks

In case 5 the daily dose was reduced from 400 mg to 300 mg after 33 weeks because the blood-pressure rose to 160/110 2 months later it was 150/100, and then it fell to 140/95 Because the urine contained a very faint trace of protein after 54 weeks' maintenance therapy, the dose was reduced by increasing the interval between courses very slowly, cortisone not being finally withdrawn until nearly a year later when all proteinuria had disappeared

Regular estimations of plasma-electrolyte levels and radiological examinations of the bones for osteoporosis were not made, but when these investigations were done no abnormalities were found, thus confirming the experience of Lange et al (1957) While on the intermittent high-dosage cortisone regimen, the children all seemed in excellent health and were remarkably free from infections In one child (case 1) lobar pneumonia developed while she was on maintenance therapy, but this responded rapidly to penicillin, and the cortisone was not interrupted Now, $3\frac{1}{4}$ to $4\frac{1}{2}$ years after starting treatment, the children all appear well and eat normal food Their heights and weights are within the limits of one standard deviation from the mean values for age The blood-pressure, and blood-urea, plasma-albumin, and plasma-cholesterol levels are normal Cases 1 and 2 show occasional traces of protein in the urine, and these children are having small doses of prednisolone (2 and 6 mg per day respectively) continuously The other three children (cases 3, 4, and 5) are not having hormone treatment, and since cortisone was finally withdrawn their urine has been free from protein for 30, 12, and 16 months respectively

Discussion

Disadvantages of the intermittent high-dosage cortisone regimen are its high cost and the possibility of troublesome side-effects

At current prices the 1200 mg of cortisone given weekly costs some six times more than the average weekly dose of 105 mg of prednisolone given in continuous treatment (Arneil 1958) Even if prednisolone in equivalent dosage is used instead of cortisone the cost is still more than twice as much Moreover, the Lange regimen is continued for at least a year even if signs of nephrosis have disappeared, whereas continuous dosage may be reduced or stopped much sooner if proteinuria has ceased. Thus the total cost of intermittent high-dosage treatment may be considerably greater

Doubt has been expressed about the safety of giving such large doses of cortisone (Kohn 1953, Rance and Chute 1955), and intermittent treatment using smaller doses of steroids has been practised in some centres (Rance and Chute 1955, Burke 1958, Kramer 1959) The Lange regimen, however, is based on doses large enough to depress antibody formation until the antigenic stimulus has disappeared, which smaller doses apparently do not achieve satisfactorily (Lange et al 1955) Twice in the present series, because the diastolic blood-pressure was persistently above 100 mm Hg, the daily dose of cortisone was reduced from 400 mg to 300 mg , but this may not have been necessary, and in each case the blood-pressure fell promptly Lange et al (1958) also found that the systolic and diastolic blood-pressure rose by 20–30 mm Hg in some of their patients, and returned promptly to normal after maintenance therapy was stopped Nevertheless, hypertensive encephalopathy is a recognised hazard of steroid therapy in nephrosis (Good et al 1957), and it is probably wise to reduce the dose if the blood-pressure is persistently high Apart from moderate elevation of blood-pressure and slight rounding of the face in some cases, no undesired effects were attributable to the steroid Lange has ascribed such freedom from toxicity to the fact that treatment is intermittent.

The risk of side-effects, therefore, cannot be regarded as an objection to this form of treatment, particularly if equivalent doses of prednisolone are used, but the cost makes it necessary to show definite advantages over other schemes before advocating its general use. Even this small series shows that complete cure cannot be claimed in all cases of the nephrotic syndrome.

Lange et al. (1955) found that none of their patients relapsed while on full maintenance therapy, this was also true of these five children, although one relapsed on maintenance treatment of less than the recommended daily dose, and another relapsed while the interval between the 3-day courses was being lengthened. But Lange et al. also had no recurrences when maintenance therapy was continued for at least a year, and their experience thus differs, for two of the five patients reported here relapsed after full treatment had been given for a year or more. It is true that these five children had severe long-standing nephrosis which was resistant to ordinary treatment, and that they might have been cured by the Lange regimen if it had been instituted at the beginning of their illness, but all the same the results do not show that this method of treatment is clearly superior

Nevertheless, these five children, who had previously been chronically ill and had spent many weeks in hospital, were able to resume normal activities and to return to school almost from starting the Lange regimen, and this in itself is a considerable achievement All five are still leading normal lives $3^1/_4$ to $4^1/_2$ years after the start of therapy, and three of them have shown no evidence of active disease for at least a year after stopping cortisone.

A most impressive feature of the Lange regimen is the remarkable physical wellbeing of the children during maintenance therapy Not only have they remained free from intercurrent infections which so often beset the child with nephrosis but they even seem to have escaped the ordinary respiratory infections of childhood. Their mothers and neighbours constantly remark how "radiant" they look. Moreover, their growth and development has not been retarded as may happen with continuous low-dosage regimes (Blodgett et al. 1956)

Thus the results of treatment in this small series suggest that intermittent high-dosage steroid therapy is worthy of trial in every case of nephrotic syndrome which has not responded to standard hormone treatment. Although cortisone is satisfactory, prednisolone in equivalent dosage would probably be preferable in the future.

Whether this regimen should always be used as the initial treatment is uncertain. It could be argued that it should be reserved as a second line of attack. Nevertheless, over a period of 65 months during which at least twelve deaths might have been expected, Lange et al. (1958) achieved very impressive results in forty-six patients, of whom only one died. They therefore advocate this regimen for all patients with nephrosis, and emphasise that mild nephrosis may not only become much more severe on relapse but also refractory to steroid therapy (Lange et al. 1957) I believe there is a strong case for instituting intermittent high-dosage steroid treatment from the outset in every case of nephrosis, but data from controlled comparisons in much larger series are needed to establish this beyond doubt.

Summary

Five children with the nephrotic syndrome who had not responded satisfactorily to one or more courses of hormone therapy were treated with large doses of cortisone given intermittently for long periods as advocated by Lange et al. (1953)

This treatment enabled all the children to resume their normal lives, and kept them well, without causing serious side-effects Three have been in complete remission for 12–30 months since treatment with cortisone was stopped, but two relapsed after maintenance treatment was withdrawn.

The Lange regimen, preferably substituting prednisolone for cortisone, is recommended for all cases of nephrosis which have not responded to other schemes of treatment, and this may be the treatment of choice for every case of nephrosis in childhood

I am grateful to Prof J L Henderson for helpful advice, and to Dr N S Clark for details of the further progress in case 3

THE QUEEN'S UNIVERSITY, BELFAST

Two doses of inactivated poliomyelitis virus vaccine (Salk type) confer about 80% protection against paralytic poliomyelitis (Medical Research Council 1957), and preliminary reports from several countries indicate that three suitably spaced doses of vaccine can give at least 90% protection. In the United States, for example, Langmuir et al. (1959) have estimated a 93% effectiveness in children up to 9 years of age and a 90% effectiveness in the 10–14 age-group, and in Canada the effectiveness of three or more inoculations has been 92% in children under 5 and 98% at ages 5–19 (Best 1959)

Although Salk's original observations showed that the antibody conversion-rate in children inoculated with a single 1 ml. dose of reference vaccine "A" was nearly 100% (Salk 1955), this does not occur with commercial batches of vaccine prepared after mid-1955 Furthermore, the injection of 1 ml. of commercial vaccine has conferred no obvious protection during the weeks following inoculation of vaccines prepared after mid-1955 (Poos and Nathanson 1956, Bundesen et al. 1957) Using vaccine prepared before mid-1955 Pope et al. (1956) claimed that 1 ml. vaccine given just before the 1955 Massachusetts epidemic was 50% effective. These differences appear to reflect the decreased potency of commercial vaccine after the introduction of manufacturing methods which ensured greater safety Be that as it may, the response to a single dose of vaccine is clearly related, among other things, to the amount of antigen administered

The experiments described below were designed to show whether a single 10 ml dose of commercial vaccine would confer protection on monkeys (cynomologus) challenged a week later with virulent type-1 poliovirus, and, if it did, whether the protection was related to the presence of demonstrable circulating antibody Such protection would suggest that inactive poliovirus vaccines of increased potency might be effective in epidemic control and might justify the use of ten-times-concentrated commercial vaccine in children during epidemic conditions until more potent commercial vaccines were available If the first dose provided a sufficient stimulus to antibody formation, protection against paralysis might be expected within a few days, instead of after the second dose three to four weeks later as is now the case In face of an epidemic this gain in time would be important

The Investigation

Materials and Methods

Tissue-culture techniques, virus isolation techniques, and serum-neutralisation tests were as previously described (Dane et al 1957)

Virus —Type-1 poliovirus Barr strain was isolated from a case of paralytic poliomyelitis in Belfast during 1958 Second monkey-kidney tissue-culture passage virus was used in the experiments

Vaccine —A British commercial formalin-inactivated poliovirus vaccine was used The antigenic extinction limit for the type-1 component was $10^{-1\cdot 2}$ estimated by Gard's method (World Health Organisation 1958) A living type-1 poliovirus (Mahoney) control with a titre of $10^{6\cdot 1}$ TCD$_{50}$ per ml gave an antigenic extinction limit of $10^{-1\cdot 6}$

Plan of Experiment

22 adult cynomologus monkeys were divided into pairs as nearly comparable in size and general appearance as possible Each pair was housed in one cage and individual monkeys were marked by tattooing numbers on their chests One monkey from each cage was allocated to the "vaccine group" and the other to the "control group" The ratio of sexes in the two groups was approximately the same Monkeys in the vaccine group were given 10 ml of vaccine by intramuscular injection into the right calf, and those in the control group were given 10 ml of the tissue-culture medium in the same site

Monkeys in both groups were at the same time given a "provoking" injection of 1 ml. procaine penicillin into the muscles of the left calf (Bodian 1956) Seven days later each monkey was challenged by the intracardiac inoculation of $10^{3\cdot 7}$ TCD$_{50}$ of type-1 poliovirus (Barr) Thereafter the monkeys were examined daily for twenty-eight days Throat and rectal swabs were taken on three occasions during the week preceding virus inoculation and thereafter daily for fourteen days Blood samples for antibody titrations (5–10 ml) were taken on the day of vaccination, one week later on the day of challenge, and finally seven weeks after inoculation. In addition smaller blood samples (2 ml) were taken every day for fourteen days after virus inoculation for virus isolation tests

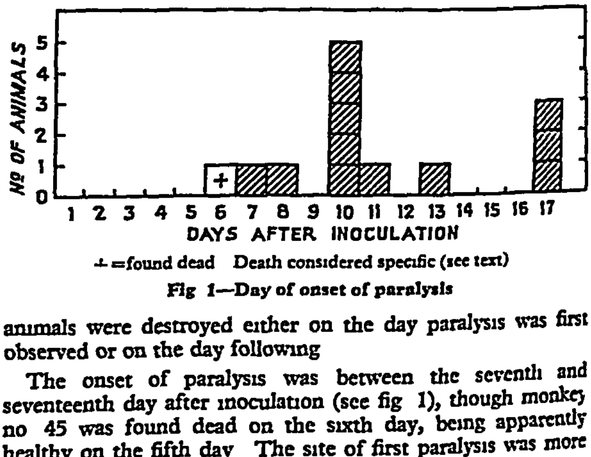
* Reciprocal of serum neutralising antibody versus 100 TCD$_{50}$ of type-1 poliovirus

All monkeys had a neutralising antibody titre of <1/4 at the start of the experiment

Results

None of the monkeys had neutralising antibody to type-1 poliovirus at the start of the experiment. One week after vaccination 8 of the 11 vaccinated animals had developed low-titre neutralising antibody (table I) 7 remained in good health during the twenty-eight days of observation and 4 became paralysed These 4 included the 3 animals which failed to develop detectable neutralising antibody In the control group 8 of the 11 monkeys became paralysed. Another (no 45) died without becoming paralysed, but, because type-1 poliovirus was isolated from its spinal cord, and the brain and cord showed typical histological lesions, its death was regarded as specific Paralysis, when present, was uniformly severe and prostrating in monkeys of both groups, and for this reason animals were destroyed either on the day paralysis was first observed or on the day following



+ =found dead Death considered specific (see text)

Fig 1—Day of onset of paralysis

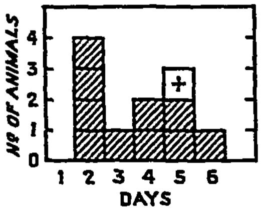
The onset of paralysis was between the seventh and seventeenth day after inoculation (see fig 1), though monkey no 45 was found dead on the sixth day, being apparently healthy on the fifth day The site of first paralysis was more commonly in the legs than in the arms or face, but in all cases it extended rapidly

Viræmia

Viræmia was found only in the monkeys which became paralysed and it lasted from two to six days (fig 2) Every specimen of serum containing virus at the screening level of detection ($10^{1\cdot 3}$ TCD$_{50}$ per ml) was titrated Titres of virus ranged from this level up to $10^{3\cdot 8}$ TCD$_{50}$ per ml, the majority lying between 10^{2} and $10^{3\cdot 5}$ TCD$_{50}$ per ml All viruses isolated from serum had the cultural appearance of poliovirus, and virus in the first positive specimen from each monkey was identified serologically as type-1 poliovirus 2 monkeys had an onset of viræmia on the day following inoculation but in the majority this occurred somewhat later and in 2 animals virus was not detected in the blood until the fourteenth day (table II) The interval between the onset of viræmia and paralysis was more uniform varying between three and eight days (fig 3)

Virus in Throat

Type-1 poliovirus was isolated from the throat of 11 of the 13 monkeys with viræmia Specimen collection ceased on the fourteenth day, which was the day on which viræmia was detected for the first time in the 2 remaining monkeys, and therefore virus may well have been present in their throats after this time. Poliovirus was not found in the throats of any of the 9 monkeys which remained healthy throughout the experiment



+=monkey died in viræmic stage.

Fig 2—Duration of viræmia.

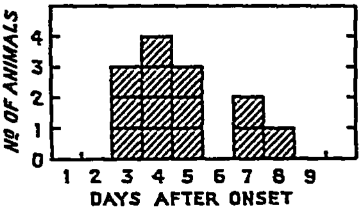


Fig 3—Onset of paralysis in relation to onset of viræmia

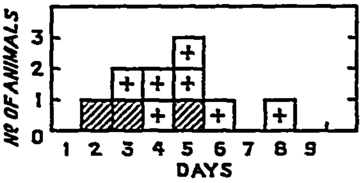


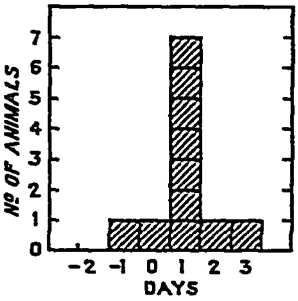
+=monkey died while excreting virus

Fig 4—Duration of throat virus excretion.

Monkey-kidney tissue-cultures were used for testing throat swabs, and, in all, nineteen isolations of cytopathogenic agents other than poliovirus were made. In no monkey were these agents found for more than two days, and they did not appear to influence the throat excretion of poliovirus or the course of the experiment. All isolates were serologically typed, but no quantitative measurements of virus were made. The duration of virus excretion in the throat was from two to eight days but many of the monkeys died while still excreting virus (fig 4) The onset of throat virus excretion was related in time to the appearance of virus in the blood (fig 5)

Virus in Gut

During the week preceding virus inoculation rectal swabs were taken on three separate occasions from each monkey and examined by inoculation into monkey-kidney tissue cultures All the monkeys were excreting cytopathogenic agents which were not polioviruses and which were not cytopathic for HeLa cells For this reason the rectal swabs taken after virus inoculation were tested for the presence of virus in HeLa cells Type-1 poliovirus was isolated on only two occasions, on the tenth day from monkey no 50 and on the eighth day from monkey no 56 It was not possible to decide whether the presence of the other enteric viruses interfered with the growth of poliovirus in the intestinal tract, but in this experiment fæcal excretion of virus was negligible in contrast to throat excretion of virus which was regular in infected animals



0=day of onset of viræmia.

Fig 5—Day of onset of throat virus excretion in relation to onset of viræmia.

Antibodies

Serum from all surviving monkeys was tested for type-1 poliovirus neutralising antibody at the end of the seventh week. Virus had not been recovered from the blood, fæces, or throat of any of these animals Monkey no 55, however, had an antibody titre of 1/45 as opposed to a titre of 1/4 one week after vaccination This rise in titre

P=Paralysis, V=Virus in blood T=Virus in throat, —=Tested and found negative. The animals bracketed shared cages.

suggests that the animal suffered from a type-1 poliovirus infection in spite of the fact that no virus was recovered from its blood, fæces, or throat The failure to recover virus may have been due to the fact that the specimen collection ceased on the fourteenth day All the other monkeys had a serum antibody titre of less than 1/4, indicating that infection had not occurred and that antibody acquired following vaccination was no longer detectable

Discussion

4 of 11 cynomologus monkeys vaccinated with 10 ml of commercial vaccine became paralysed after intracardiac challenge with 10^{4} TCD$_{50}$ of virulent type-1 poliovirus given one week after vaccination By comparison the paralytic attack-rate in the control group was about twice as high, 9 out of 11 monkeys becoming paralysed As will be discussed later, some cross-infection may have occurred between control and vaccinated monkeys This would almost certainly have had the effect of increasing the challenge to the vaccinated monkeys, thus reducing the calculated effectiveness of the vaccine 3 monkeys in the vaccinated group failed to develop antibody in response to vaccination and all these animals became paralysed The 1 other paralysed monkey in the vaccinated group had low-titre antibody at the time of challenge, and, like all the other paralysed monkeys from which suitable specimens were obtained, had a viræmia and also excreted throat virus Of the 8 which developed antibody as a result of vaccination, this was the only monkey that became paralysed Thus among vaccinated monkeys which developed detectable antibody following vaccination there was a significantly lower incidence of paralysis than among the unvaccinated control animals (double tail P=0 006)

In previous experiments we have found it difficult to induce regular alimentary infection in cynomologus monkeys by inoculating virus (type-1 Barr or Mahoney) into the stomach with a catheter A total of 16 monkeys were inoculated with large amounts of virus in this way and only 5 developed paralysis, in addition, the results from experiment to experiment were variable This failure to infect cynomologus monkeys regularly by stomach-tube with virulent polioviruses may have been due to interference by other enteric viruses Perhaps a more likely explanation is that the alimentary tract of cynomologus monkeys is relatively much less susceptible to poliovirus infection than the pharynx We are inclined to believe that the irregular and low infection-rate in cynomologus monkeys which were inoculated via the stomach was probably due to a varying degree of contamination of the pharynx with virus during passage of the catheter

In the experiment reported above we would have preferred to challenge the monkeys by the oral route, and might have been successful in this if we had placed the virus in the mouth However, we used the intracardiac route of inoculation because of the difficulties involved in introducing an accurate amount of virus into the mouth and because we did not realise how regularly the virus would parasitise the throats of cynomologus monkeys

Paralysis, and in 1 monkey death without paralysis being observed, was preceded by viræmia and multiplication of virus in the throat Throat virus was associated with viræmia, and if these were absent paralysis did not occur In all monkeys which became paralysed and from which suitable specimens were taken, throat virus was detected (This included all monkeys except 2 in which viræmia was not detected till the fourteenth day) In 7 of the 11 monkeys adequately tested, throat virus was demonstrated the day after the first detection of viræmia (fig 5) This might suggest that multiplication of virus in the throat was in general initiated as a result of viræmia. However, it must be emphasised that the method for detection of blood virus was probably 10–100 times more sensitive than could be used for throat virus If it had been possible to use equally sensitive techniques the appearance of throat virus might have been shown to precede viræmia, and indeed this would seem quite a logical sequence of events

Paralysis did not occur in the absence of viræmia, but all monkeys with viræmia developed a severe and prostrating paralysis It is not possible to say whether the provocative injection of penicillin was in any way responsible for this or whether marked invasiveness was a property of the strain we used It shows, however, that at least under certain conditions, the central nervous system of cynomologus monkeys is more susceptible to poliovirus than that of man

Although careful precautions were taken while handling the monkeys to prevent cage-to-cage cross-infection, contact could naturally not be avoided between the monkeys caged together in pairs

In three of eleven cages both monkeys were paralysed (nos 50 and 51, 58 and 59, 60 and 65, see table II), and it seems unlikely that if cross-infections occurred between these monkeys they could have occurred other than by throat virus In these three cages, each with 2 paralysed monkeys, the intervals between virus inoculation and the onset of paralysis were not outside the possible range, but the long incubation periods of seventeen days and the difference in the time of the onset of paralysis in the cage-mates make contact infections a possibility If contact infections did occur one would expect throat virus to be present before blood virus In fact, this was not found, but because of the lower sensitivity of the test for throat virus we cannot take the failure to isolate virus first from the throat, before its demonstration in the blood as evidence against contact infection.

The important part which throat virus seems to play in the pathogenesis of poliomyelitis in cynomologus monkeys suggests that, when considering the spread of poliovirus in man, pharyngeal virus should not be dismissed as unimportant Although we have shown that contact infection with an attenuated poliovirus can occur between children in the absence of throat virus (Dick et al 1957), we still think that throat virus may play an important part in the dissemination of virulent polioviruses in the community

While our experiments with cynomologus monkeys were in progress, the antibody response of adults and children to inoculation with 10 ml of commercial vaccine was tested by Baron et al (1959) They showed that all of 5 non-immune adults and 5 of 7 non-immune children who were inoculated with 10 ml of a commercial vaccine had circulating antibody to type-1 poliovirus two weeks after immunisation The rate of conversion among the triple-negative children whom they studied (5 of 7) was similar to the rate we obtained in cynomologus monkeys (8 of 11)

Although the pathogenesis of infection in cynomologus monkeys may be different from that in humans, it seems reasonable to assume that the rapid development of low-titre antibody in children produced by a single large dose of antigen would have a protective effect against virulent virus similar to that which we have observed in cynomologus monkeys

The practical application of these studies relates to the possibility of using more potent inactivated Salk-type vaccine (or larger doses of current commercial vaccine) in the face of an epidemic.

We consider there is evidence that low-titre circulating antibody affords protection against poliomyelitis, and that this antibody can be obtained with a single dose of inactivated vaccine, provided that the amount of antigen given is sufficient. The speed with which protection is conferred is likely to be rapid, and subsequently the normal course of injections could be given, counting the "emergency" dose as the first dose

Summary

A proportion of cynomologus monkeys given a single 10 ml dose of commercial poliomyelitis vaccine (Salk type) developed low-titre neutralising antibody, and these animals were protected when challenged one week later with a virulent strain of type-1 poliovirus

Single large doses of inactivated vaccine might give useful protection in an epidemic.

In the pathogenesis of poliomyelitis in cynomologus monkeys, throat virus seems to play an important part. It may be equally important in the dissemination of the disease in man

This investigation was supported by a grant from the National Fund for Poliomyelitis Research and the Medical Research Council

We wish to acknowledge the assistance given by Brian McFerran, M.R.C.V.S , and James P Evans and Laurence Corkin (student technicians) in the care and handling of the monkeys and by Mr Fred Burns (chief technician)

X-RAY STUDY OF PASSAGE OF AIR THROUGH THE PHARYNX IN ANÆSTHETISED PATIENTS

H Ruben
Cand Med Copenhagen
DIRECTOR, ANÆSTHESIA DEPARTMENT

N Bentzen
Cand Med Copenhagen
FIRST ASSISTANT, RADIOLOGY DEPARTMENT
FINSEN INSTITUTE, COPENHAGEN

S K Saev
M.D Sofia
WORLD HEALTH ORGANISATION FELLOW,
ANÆSTHESIOLOGY CENTRE, COPENHAGEN

This investigation was performed to establish the influence of the position of the head and jaw on the patency of the air-passage at the level of the tongue. 21 patients, all under general anæsthesia before operation, curarised, and deeply relaxed and apnœic, were examined radiographically in the supine position 12 of the 21 were similarly examined when awake.

Method

12 patients had lateral views taken in the following three positions during anæsthesia and when awake (1) with the head tilted back by maximal extension in the upper part of the cervical spine, (2) with the head in normal position (i.e. with the pupil axis vertical) without attempt to extend or flex the neck, (3) with the neck flexed, the head supported by a pillow 8 cm high

In a deeply relaxed patient the mouth opens during maximal backward tilting of the head because of the pull of the tissues in front of the neck. In 10 patients radiographs were taken when, during the backward tilting, the patient's mouth was closed by pushing up the chin in the midline

11 patients had lateral views taken with the head tilted backwards by extension in the uppermost part of the cervical spine, and additionally during application of the following 3 manœuvres (1) the mouth closed by pushing the chin up against the maxilla, (2) the mandible pushed forwards by pressure applied forcefully on both sides behind the ramus of the mandible, (3) the mandible pulled forwards forcefully with a finger in the patient's mouth behind his lower front teeth

To find out the importance of extension itself, in 6 patients radiographs were taken during these same three manœuvres, but with the patient's head in the normal position.

Finally, in a few cases X-rays were taken during anæsthesia with the patient's head hanging over the edge of the operating-table.

Results

The results are shown in the accompanying table The distances between the pharyngeal wall and the back of the tongue, and between the pharyngeal wall and the epiglottis, are in each case the smallest clearances seen As the front-back clearance (unlike the transversal clearance) varies substantially, this clearance is taken as an expression of the patency of the pharynx.

In this account *complete obstruction* denotes that no air space at all was seen on the X-ray picture between the pharyngeal wall and the tongue. *Partial obstruction* denotes that the clearance was at most 3 mm , *satisfactory air-passage* that there was clearance of 5–6 mm., and a *very good air-passage* that there was a 7 mm. or larger clearance 5 mm was chosen as indicating satisfactory air-passage because this was the smallest clearance found in any awake patient in this study

With the *patients awake* there was in every instance a clearance of 5–20 mm at the levels of the tongue and the epiglottis Usually it was slightly smaller when the head was tilted forwards than in the normal position When the head was extended there was in every instance an increase in the clearance both at the tongue and at the epiglottic level of the pharynx, the clearances varying between 8 and 25 mm

Of the 12 *anæsthetised patients* with the *head flexed*, at the level of the tongue complete obstruction was found in 8 cases, and partial obstruction in 2 cases With the head in the normal position complete obstruction was found in 4 of 12 cases, and partial obstruction in a further 4 Clinically, therefore, one might expect to find obstruction at the tongue in 10 out of 12 cases when the head is flexed, and in 8 out of 12 cases when the head is in the normal position In only 1 case was a satisfactory air-passage found at the tongue in both the flexed and the normal positions At the epiglottic level, with the head flexed, no clearance was found in 8 cases and a clearance of only 2 mm or less in the other 4 cases With the head in the normal position no air space was seen in 4 cases, and an air space of 3 mm or less in 6 cases

With the head of the anæsthetised patient tilted back, CLEARANCES (MM) BETWEEN PHARYNGEAL WALL AND TONGUE, AND BETWEEN PHARYNGEAL WALL AND EPIGLOTTIS

a, mouth closed by pushing chin up
b, mandible pushed forwards by pressure behind each ramus
c, mandible pulled forwards with thumb in mouth behind lower front teeth

1, head in normal position
2, head tilted back maximally

a patent air-passage was found in every instance, in 8 of the 12 cases the air-passage was very good and in 4 cases satisfactory When, with the head in this extended position, the chin was pushed up so that the mouth was closed, this usually increased the clearance notably in 10 of the 12 cases it was then even larger than, and in 2 cases about the same as, in the same patient when awake with the head in the normal position In the extended position a larger clearance was always found at the epiglottis than at the tongue

In 11 of the patients, in whom the effect of different mandible manœuvres with the head in the extended position was compared, this effect agreed with that found in 8 other patients in this investigation closing the mouth notably enlarged the clearance between the pharyngeal wall and the tongue and between the pharyngeal wall and the epiglottis Pulling forwards the body of the mandible or pushing forwards the ramus of the mandible at each side usually, but not in every case, gave a larger clearance than did the combined manœuvre of extension and pushing the jaw up against the maxilla This was so, however, only when with the forward displacement of the jaw the head was tilted maximally back, otherwise the clearance was much the same with all these manœuvres

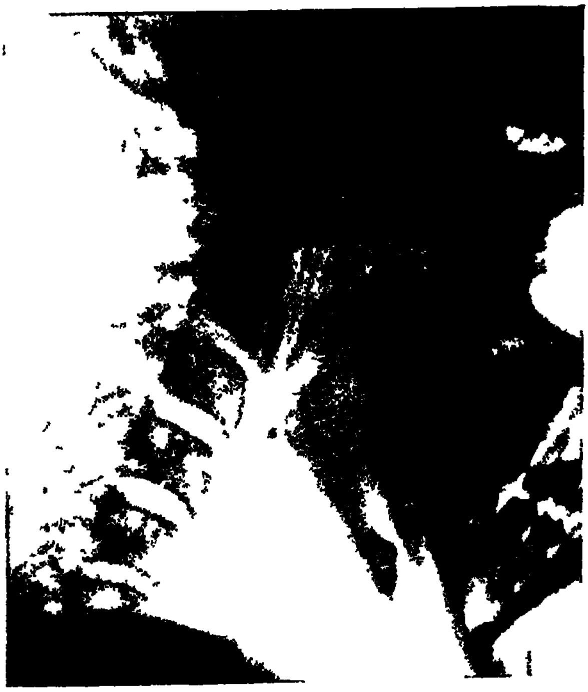

Fig 1—Anæsthetised patient: head flexed; no clearance between tongue, epiglottis, and pharyngeal wall

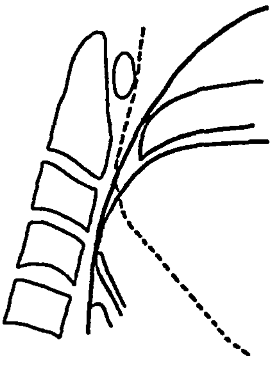
Air-passage at Soft Palate

In 10 *waking patients* the air-passage between the soft palate and the tongue, and between the soft palate and the pharyngeal wall, was examined In 9 of the 10 patients no air space was seen between the tongue and the palate, an in 1 case no air space between the palate and the pharynx

Of the 19 *anæsthetised patients* in the extended position with the jaw pushed up, in 5 there was no air space between the soft palate and the pharyngeal wall, and in 6 no air space between the soft palate and the tongue

Between the palate and the pharynx no air space was seen in 3 out of 11 cases when the mandible was pushed forwards behind the ramus, and in 4 of these 11 when the body of the mandible was pulled forwards Between the palate and the tongue, and between the palate and the pharynx, no air space was seen in 1 case and in no case, respectively



Discussion

This study shows clearly that the position of the head is important for the patency of the air-passage through the pharynx While in all the waking patients there was an open air-passage independently of the position of the head, this was not so in the anæsthetised, curarised patients. With the head in the flexed position obstruction was found in almost all the patients. Of 12 patients the only 2 who then showed an open air-passage at the tongue level showed no air space at the epiglottis With the head in the normal position only 2 of the 12 patients showed an open air-passage at the tongue as well as the epiglottis; 2 more showed a small clearance at the epiglottis, but none at the tongue; and in 8 no air space could be observed at the tongue or at the epiglottis

With the head extended each of the 12 anæsthetised patients showed a satisfactory air-passage, and in 7 of these it was very good both at the tongue and at the epiglottis. With the head in the hanging position an air passage was produced only if the backward tilt resulted in extension of the upper part of the cervical spine, extension of the lower part alone did not have this result.

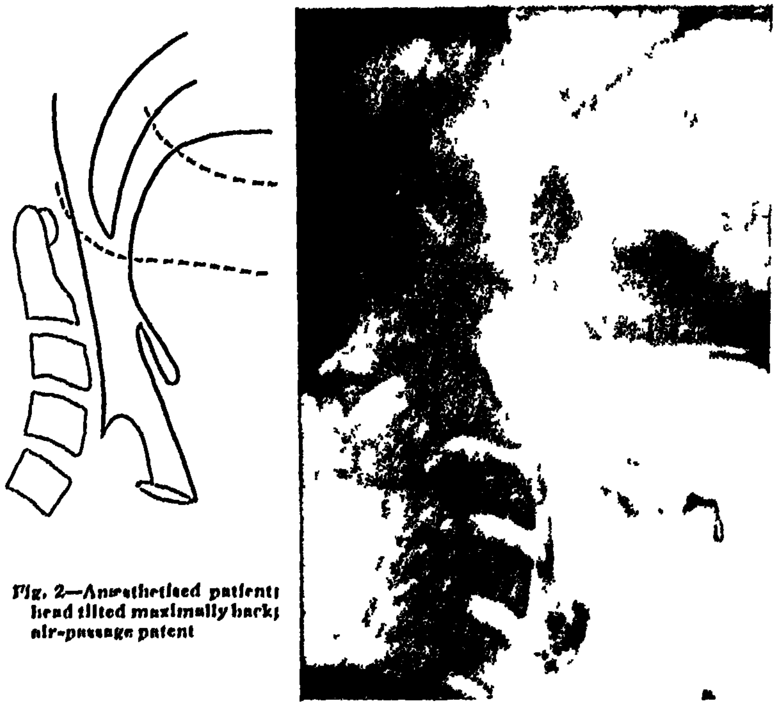


Fig. 2—Anæsthetised patient: head tilted maximally back; air-passage patent

Tilting the head back, and in addition closing the mouth by pushing the jaw up against the maxilla, substantially increased the clearance at the epiglottis and at the tongue level, in each of 19 patients very good clearance was found during this combined manœuvre. The clearance thus produced was even larger with the patient under anæsthesia than when awake with the head in normal position.

Before and in the intervals between radiography the patients were ventilated with bag and mask, keeping the head tilted back and the chin pushed up. At these times there was clinically in every case an open air-passage, even where the radiographs showed no air space between the soft palate and the tongue or between the soft palate and the pharynx. It therefore seems that this finding has no practical importance. The reason for the discrepancy is probably that the pliable soft palate is moved out of the stream by the moving air

Extension of the head with closure of the mouth was found to give practically the same opening of the air-passage as pulling or pushing the mandible forwards with the head kept in the normal position Even when the head was tilted maximally back, the clearances found were only some 25% greater with forward displacement of the jaw. Independently of which technique was used, the clearance established was always greater than the front-back clearance seen in the larynx, so with the respiratory rates normally existing, these relatively minor variations could probably be considered as of no practical importance.

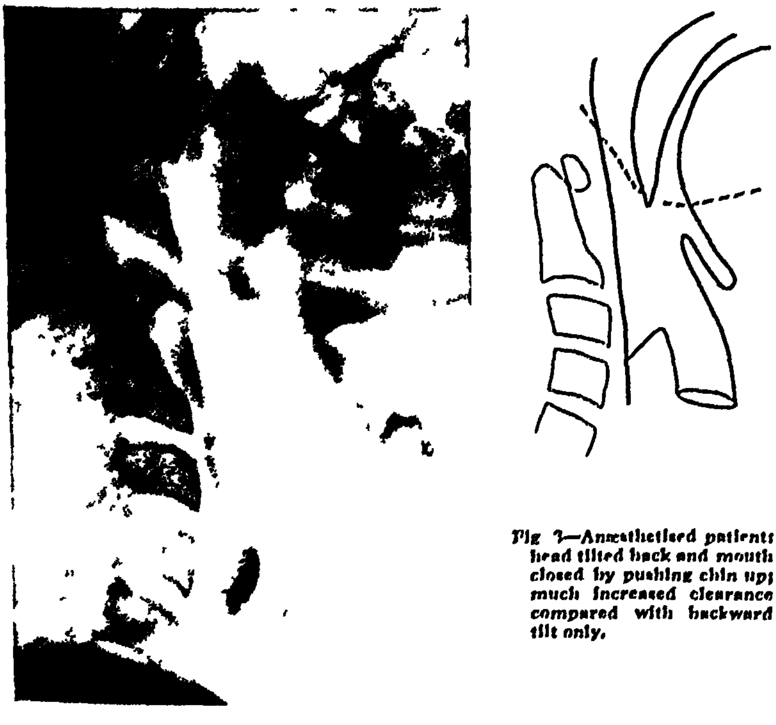

Fig 3—Anæsthetised patient: head tilted back and mouth closed by pushing chin up; much increased clearance compared with backward tilt only.

Conclusions

In the unconscious patient the air-passage through the pharynx is usually maintained by moving the mandible forwards. This study has shown that patency is obtained by merely tilting the head back, thereby producing extension of the upper part of the cervical spine. When, in addition, the patient's mouth is closed, clearance is substantially increased, making a very good air-passage Application of these manœuvres to anæsthetised patients, during spontaneous respiration as well as during apnœa, has shown this method to be effective clinically, and it has proved of practical importance when using a facemask during anæsthesia. It has also been used during expired-air resuscitation, when it was found that laymen more easily learnt this technique than that of the usual forward displacement of the jaw.

VENOARTERIAL SHUNTS IN CIRRHOSIS OF THE LIVER

JOHAN GEORG
M D Copenhagen

KRESTEN MELLEMGAARD
Cand Med Copenhagen

NIELS TYGSTRUP
Cand Med Copenhagen

KJELD WINKLER
Cand Med Copenhagen

From Rigshospitalet, Copenhagen

CYANOSIS and clubbed fingers have occasionally been noted in patients who have cirrhosis of the liver but no demonstrable disease of heart or lung. Snell (1935) and Keys and Snell (1938) were the first to demonstrate a decrease of arterial oxygen saturation in cirrhosis, finding it in 48 of 61 cases. Later workers have observed this decrease with varying frequency, but generally much less often (Darling, 1940, Claypool et al. 1957, Murray et al. 1958). In 28 consecutive cases investigated by us the oxygen saturation was below 93% on one or more occasions in 14.

The aim of the present study was to ascertain whether venoarterial shunting of blood is a cause of this arterial unsaturation.

Methods

In 19 patients admitted to medical department B of Rigshospitalet, the diagnosis of cirrhosis was established clinically and by laboratory tests, being confirmed histologically (liver biopsy or necropsy) in 18. Only 3 had chronic alcoholism. In the 9 subjected to cardiac catheterisation normal findings were recorded in the hearts.

For comparison, 17 patients without signs of hepatic, cardiac, or pulmonary disease were studied, 4 of them having cardiac catheterisation.

The examination was made in the fasting state, with the patient supine. Blood was collected in oiled heparinised syringes from an indwelling arterial needle. The patient then breathed pure oxygen, or 50% oxygen in nitrogen, for twenty minutes, after which blood was again collected. Expired air was sampled for oxygen and carbon-dioxide content before and during the inhalation of oxygen.

The patients subjected to cardiac catheterisation were premedicated with phenobarbitone 200 mg. Blood was drawn from the pulmonary artery simultaneously with the arterial sampling. For assessment of the degree of portal hypertension, wedged hepatic venous pressure was obtained before the inhalation of oxygen.

Analytical Procedures

The oxygen tension was measured polarographically with a dropping mercury electrode (Bartels 1951, Bartels and Laue 1951). Each result given is the average of three separate determinations. Individual calibration curves were produced by equilibrating blood from each patient for twenty minutes with three gas mixtures containing varying amounts of oxygen and nitrogen, and 5% carbon dioxide. The coefficient of variation of the method is about 2% at physiological oxygen tensions and about 4% at high tensions.

The carbon-dioxide tension of the samples was calculated from determinations of pH of the blood before and after equilibration with carbon dioxide at a tension of 40 mm. Hg (Astrup 1957).

Oxygen saturation was determined with the Brinkman hæmoreflector (Zijlstra 1953), and oxygen content was calculated from oxygen saturation and from oxygen capacity (derived from a photometric determination of the hæmoglobin concentration).

Gas analysis was performed on the Haldane apparatus.

Calculation

For calculations of the venoarterial shunt the following equation was used (cf. Comroe et al. 1955):

$$\frac{Qs}{Q} = \frac{Cc'_{O_2} - Ca_{O_2}}{Cc'_{O_2} - C\bar{v}_{O_2}}$$

where

$\frac{Qs}{Q}$ = ratio of venoarterial shunt to cardiac output.

Cc'_{O_2} = oxygen content of pulmonary end-capillary blood.

This last value is derived from the alveolar oxygen tension, which during oxygen inhalation is considered identical with the end-capillary oxygen tension. The alveolar oxygen tension is calculated from the Bohr equation, taking arterial carbon-dioxide tension as representing mean alveolar carbon-dioxide tension.

Ca_{O_2} = oxygen content of arterial blood (oxygen capacity plus physically dissolved oxygen).

$C\bar{v}_{O_2}$ = oxygen content of mixed venous blood.

The oxygen content of mixed venous blood was measured during cardiac catheterisation or estimated from an assumed arteriovenous oxygen difference of 4·5 vol. %.

Results

Estimation of venoarterial shunt in the 17 control patients (table I) shows an average value of 2·5% of the cardiac output, with a standard deviation of 1·6%. This, according to the *t* test, signifies that 95% of normal subjects will have shunts below 6%. These values agree well with those in the literature.

Table II shows that 12 of the 19 patients with cirrhosis had venoarterial shunts above the value regarded as the upper limit of normal.

In the first part of table II, comprising patients subjected to cardiac catheterisation, two values of the relative venoarterial shunt are listed, one based on the measured arteriovenous oxygen difference, the other on an estimated difference of 4·5 vol. %, which is used in the patients not catheterised. As the arteriovenous oxygen difference in cirrhosis of the liver is often below this "normal" value, because of increased cardiac output, the shunts recorded in the second part of table II—from patients not catheterised—tend to be minimal values.

In our experience the degree of arterial unsaturation in

† Values obtained during respiration in 70% oxygen

cirrhosis shows great fluctuation. Whether the same is true of the venoarterial shunt cannot be stated with certainty, but the few repeated shunt determinations—generally performed after an interval of several months—have shown remarkably constant values

None of the clinical and laboratory data in table III can be correlated with the presence or magnitude of an abnormal venoarterial shunt.

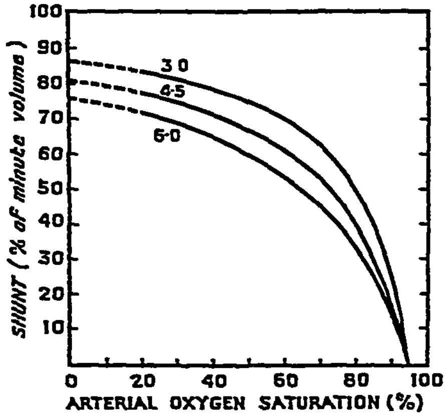
Discussion

The alveoloarterial oxygen gradient, existing during respiration in atmospheric air, may be due to uneven distribution of the inspired air to different parts of the lungs (resulting in regional hypoventilation), to difficulties in diffusion, or to venoarterial shunt. During respiration in oxygen the distribution and diffusion factors are eliminated, and if there is still an alveoloarterial oxygen gradient it must be due to a venoarterial shunt.

The pioneer work on the present method of shunt estimation was done by Berggren (1942) and the method has been used extensively by Bartels and his associates (Bartels et al 1955, Rodewald et al 1956) Wilson et al. (1953) using Berggren's method, noted an average shunt of 5·8% (standard deviation 2·9%) in 10 patients with cirrhosis

The observation of cyanosis and clubbing of the fingers in this disease goes back to Flückiger (1884), followed by Gilbert and Fournier (1895), Boutron (1899), Hijmans van den Bergh (1901), and Gilbert and Lereboullet (1902) It was made chiefly in cases of biliary cirrhosis or juvenile cirrhosis

The observed high incidence of abnormal venoarterial shunts in cirrhosis indicates that this is an essential factor in the arterial unsaturation previously noted in this disease. Our data do not permit a definite quantitative evaluation. Only fairly large shunts can reduce the arterial oxygen saturation significantly, as depicted in the chart, which shows the calculated effect of venoarterial shunting on the arterial oxygen saturation in a patient with an oxygen capacity of 20 vol % and initially 95% arterial oxygen saturation, and a constant cardiac output. Abnormal oxygen dissociation for the hæmoglobin of patients with cirrhosis was demonstrated by Keys and Snell (1938) This may contribute to the arterial oxygen unsaturation, but in most cases a venoarterial shunt seems to be a sufficient explanation.



Influence of venous-to-arterial shunt on the oxygen saturation of the arterial blood.

The curves are calculated assuming a constant cardiac output and arteriovenous oxygen difference (3·0, 4·5, or 6·0 vol %), and an arterial oxygen saturation of 95% initially

The location of the shunt is uncertain. Atelectasis of the lungs, caused, for example, by pleural effusion or ascites, will result in venoarterial shunting (i e., perfusion of unventilated parts of the lungs), but in our material (table III) such features have not been prominent.

Rydell and Hofbauer (1956) demonstrated venoarterial shunts by postmortem casts of the pulmonary vessels in a patient with juvenile cirrhosis This patient was found to have numerous minute arteriovenous anastomoses in the lungs, and these were regarded as pulmonary spider nævi Hales (1956), using a similar technique, also demonstrated pulmonary arteriovenous fistulæ in a patient with cirrhosis, but he regarded these as evidence of Rendu-Osler-Weber disease, in which pulmonary arteriovenous anastomoses are common and may be demonstrated by pulmonary angiography This technique failed to reveal any abnormality in 2 cases of cirrhosis studied by Murray et al (1958), and in one of our cases (no 10) This patient, who had the biggest shunt of the series, died later in the hospital No casts were made, but on routine examination the lungs appeared normal macroscopically and histologically

Another cause of venoarterial admixture was demonstrated by Calabresi and Abelmann (1957) and by Schoenmackers and Vieten (1957) By postmortem injection they demonstrated abnormal communications from the portal vein via the periœsophageal and mediastinal veins to the bronchial and pulmonary veins These anastomoses are presumably pre-existing channels which the portal hypertension brings into use

This appears to be the most likely explanation of the arterial unsaturation in patients with cirrhosis In this respect determination of venoarterial shunts in patients with portal hypertension from extrahepatic causes will be particularly interesting It should be noted that the size of a shunt through these channels is underestimated with the method we used, because the oxygen saturation of the blood from the portal vein tends to be higher than that of the mixed venous blood from the right heart

Summary

Venoarterial shunt has been estimated in 19 patients with cirrhosis of the liver, using polarographic measurement of arterial oxygen tension during oxygen breathing The shunts averaged 9 5% of the cardiac output, and were in 12 cases found to be above the 6% that is regarded as the upper normal limit with the present technique

The heart catheterisations were performed in the cardiological laboratory of medical department B, Rigshospitalet We wish to thank Prof Erik Warburg and Dr A Tybjærg Hansen for their help and advice

EFFECT OF CORTISONE ON THE EXCRETION OF ALDOSTERONE IN VIRILISING ADRENAL HYPERPLASIA

J DE GRAEFF
M.D Leiden

A J MOOLENAAR
D Sc. Leiden

From the Department for Clinical Endocrinology and Diseases of Metabolism, University Hospital, Leiden, Holland

IN 1955 Prader et al reported a raised level of aldosterone in the urine of some patients with the adrenogenital syndrome caused by congenital adrenal hyperplasia (" virilising adrenal hyperplasia ") In 1959 Blizzard et al published measurements of aldosterone excretion in a large number of patients with virilising adrenal hyperplasia They found normal or large amounts of aldosterone in the urine of those without associated salt-loss, but little or no aldosterone in the urine of those with a salt-losing syndrome

As no data seem to be available on the influence of cortisone on aldosterone excretion in this syndrome, we describe and discuss here the results of a study made in 1956 (de Graeff and Moolenaar 1957)

Investigation

Patient A, aged 14, was a typical case of virilising adrenal hyperplasia in the *female* A laparotomy in *1947* had demonstrated a uterus and ovaries Patient B, aged 8, was a typical case of this disorder in the male, presenting as macrogenitosomia præcox Neither patient had ever displayed the salt-losing syndrome

Aldosterone excretion was measured by the method of Moolenaar (1957) (normal values 2–12 µg per day) Neutral 17-ketosteroids were measured by the method of Kassenaar et al (1950) Otherwise routine laboratory methods were used. Patient A received a constant diet, containing a calculated daily amount of 175 mEq of sodium and 90 mEq of potassium Patient B did not receive a constant diet, because lack of cooperation made this impossible

The excretion of neutral 17-ketosteroids and aldosterone was measured at intervals In patient A the urine was collected daily, and the excretion of sodium and potassium was measured throughout the study

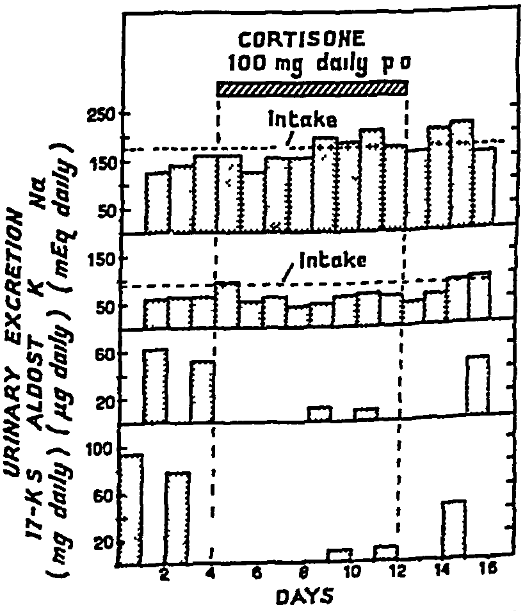

Fig 1—Effects of cortisone (100 mg daily) in patient A on a constant diet.

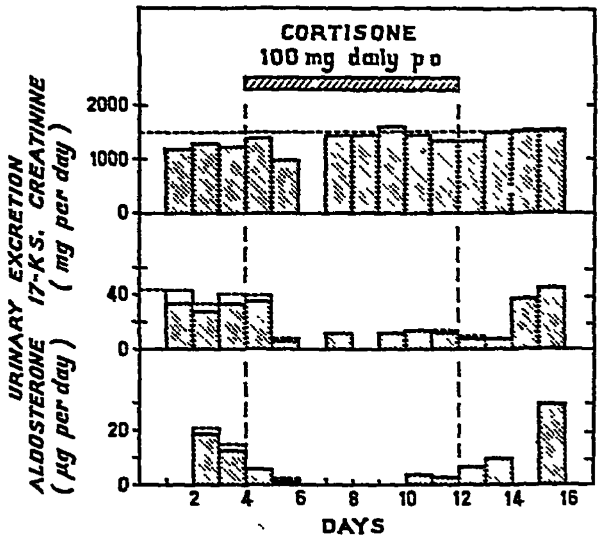

Fig 2—Effects of cortisone (100 mg daily) in patient B

According to the level of creatinine excretion in the urine not all urinary collections appear to have been complete. The amounts of neutral 17-ketosteroids and aldosterone in the urine have been corrected for this (interrupted lines), taking an average daily amount of 1500 mg of creatinine as normal for this patient.

Both patients received 100 mg of cortisone by mouth, divided into four equal doses, daily for 8 days

As would be expected, their excretion of neutral 17-ketosteroids fell to normal After cessation of cortisone administration the excretion of 17-ketosteroids returned to pre-treatment levels in patient B, and rose significantly in patient A within 2 days

Patient A excreted very large amounts of aldosterone (62 and 51 µg per day) at the beginning of the study During the administration of cortisone high normal values (12 and 10 µg) on the 6th and 8th day were obtained. On the 3rd day after stopping the treatment the high value of 50 µg was found again (fig 1)

In patient B the excretion of aldosterone was moderately raised (18 and 13 µg per day) before cortisone was given. It fell to a low normal level within 2 days of commencement of cortisone treatment (2 µg per day) and remained there till cortisone treatment was stopped (fig 2) It then rose again, reaching a high level (28 µg per day) on the 4th day The fact that, judging by creatinine excretion, not all urinary collections were complete does not invalidate this statement.

The data on the excretion of sodium and potassium in patient A are rather inconsistent. There was perhaps a small increase in the amount of urinary sodium towards the end of the cortisone period, but this persisted after administration of cortisone was stopped. The excretion of potassium was more or less constant, with a small peak on the first day of cortisone administration and a small increase 3 days after this ceased.

Neither patient showed any clinical changes, subjective or objective, during the administration of cortisone

Discussion

The two patients both excreted abnormally large amounts of aldosterone on a normal salt intake, and there seems to be no doubt that cortisone reduced their aldosterone excretion to normal levels

In four patients without associated salt-loss, Blizzard et al (1959) did not find that cortisone reduced aldosterone excretion, but, as they do not give any pre-treatment values, no definite conclusions can be reached.

Assuming that urinary aldosterone levels reflect the rate of secretion of this hormone, the effect of cortisone on aldosterone excretion can be explained in two ways

Crigler et al (1952) have suggested that in patients with virilising adrenal hyperplasia there is a "sodium-losing" factor, which is corticotrophin-dependent. The loss of sodium and thus of extracellular fluid would be a stimulus to aldosterone secretion, increase of which would counteract the sodium-losing factor On this hypothesis, proposed by Prader et al (1955), a patient with a salt-losing syndrome would be "uncompensated" whereas a patient without salt-loss would be compensated This would explain why some patients have a salt-losing syndrome in their youth but seem to overcome this later Our two patients might then be regarded as compensated cases Cortisone, by inhibiting the secretion of corticotrophin, would reduce the production of the salt-losing factor, thus removing the stimulus for increased aldosterone secretion. It is difficult to say what would happen to sodium and potassium excretion in such circumstances The decrease in the effect of the salt-losing factor would tend to inhibit sodium excretion, but the fall in aldosterone secretion would tend to stimulate it

There are objections to this explanation. The concept of a sodium-losing factor does not seem physiological, and the existence of such a factor has never been demonstrated conclusively Moreover, patients with virilising adrenal hyperplasia without an associated salt-loss (especially those who had had the salt-losing syndrome in their youth) should show a raised aldosterone excretion Yet, according to the data of Blizzard et al (1959), they do not always do so Considering that a defect of hydroxylation at C_{21} is supposed to be the cause of virilising adrenal hyperplasia, it is rather surprising that any aldosterone can be produced at all Different degrees of the enzymatic defect (Bongiovanni 1955) or a difference in distribution of the defect in the adrenal cortex might explain the exceptions cited above.

Alternatively one might develop another explanation Under the influence of cortisone the changes in the excretion of 17-ketosteroids and of aldosterone seem to occur simultaneously, and this might suggest an identical mechanism If, like the raised 17-ketosteroid excretion, the raised aldosterone excretion were due to a rise in the secretion of corticotrophin, cortisone would inhibit it in the same way Here again one would have to invoke a different degree of defect in hydroxylation at C_{21} to explain why in some cases a high level of 17-ketosteroids and a low level of aldosterone are found in the urine.

There are many arguments against this explanation The dependence of aldosterone secretion on corticotrophin is only very slight It would not explain why exogenous corticotrophin may produce sodium diuresis in these patients and why the amounts of desoxycorticosterone needed to control the salt-loss patients are greater in untreated than in cortisone-treated patients

More work will have to be done to decide this issue, but the inhibition of aldosterone excretion by cortisone will have to be taken into the account.

Summary

A raised level of aldosterone excretion was found in two patients with virilising adrenal hyperplasia. Cortisone reduced it to normal levels The implications are discussed

MEDICAL UNIT, ST GEORGE'S HOSPITAL, LONDON, S W 1

Kekwick and Pawan (1953, 1956) stated that, during short periods on isocaloric sub-maintenance diets, weight loss was greater when most of the calories were supplied by fat than when most were supplied by carbohydrate Since they had not observed failure to absorb fat, or changes in basal metabolic rate, they suggested that this difference was due to a specific dynamic action of fat much larger than had previously been observed Unfortunately, their findings have been used by others as a basis for slimming diets, an extrapolation which does not at present seem justified We have therefore thought it important to repeat these experiments for longer periods

Methods

Our study was carried out in the metabolic unit, where the patients were isolated from the general ward population Full balance techniques were used, with total urine and fæcal collections, in six-day periods Full details of the chemical balances will be reported elsewhere The diets were constructed from the tables of McCance and Widdowson (1946), and each was analysed at least once for fat and nitrogen The analyses agreed with the calculated values within 10%

The patients, 7 women and 2 men, were all grossly obese by any standard They were weighed at the same time each morning Exercise was not controlled but was minimal In a preliminary experiment on one other patient on an 800-calorie diet of varying composition, there was a linear fall in weight over a period of four months—from 103 to 78 kg At this degree of obesity we felt quite happy to allow lengthy periods on each diet

Experiment I (4 patients 800 calories)

Patient 1	Male, aged 50	96 kg
Patient 2	Male, aged 52	80 kg
Patient 3	Female, aged 44	106 kg
Patient 4	Female, aged 59	85 kg

Patients 1 and 2 started on a mixed diet and then continued with patients 3 and 4 to take the following diets alternately for periods of eighteen days

Protein (% calories)	*Fat (% calories)*	*Carbohydrate (% calories)*
13	9	78
15	62	23

Total water was constant for each patient at chosen level but differed in the two diets Salt ad libitum

Experiment II (2 patients 1000 calories)

Patient 5	Female, aged 54	94 kg
Patient 6	Female, aged 39	147 kg

The diets were alternated every twenty-four days

Protein (% calories)	*Fat (% calories)*	*Carbohydrate (% calories)*
17	8	75
17	70	13

Total water was constant for each patient at chosen level (1 6 litres, 1 8 litres) Sodium was constant for each patient at chosen level (1 8 g, 2 3 g)

Experiment III (3 patients 1000 calories)

Patient 7	Female, aged 49	111 kg
Patient 8	Female, aged 28	109 kg
Patient 9	Female, aged 52	127 kg

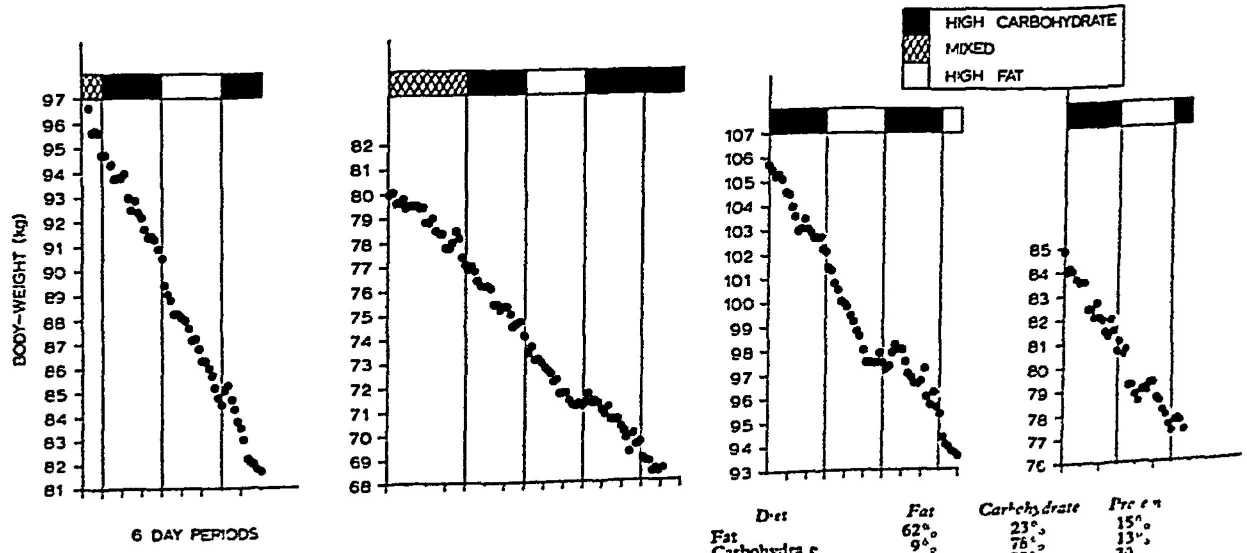
The following diets were alternated every twenty-four days (patient 9 started on a mixed diet)

Protein (% calories)	*Fat (% calories)*	*Carbohydrate (% calories)*
5	4	91
5	86	9

Total water was constant for each patient at chosen level (1 9 litres, 2 1 litres, 1 8 litres) Sodium was constant for each patient at chosen level (1 5 g, 2 5 g, 2 5 g)

Results

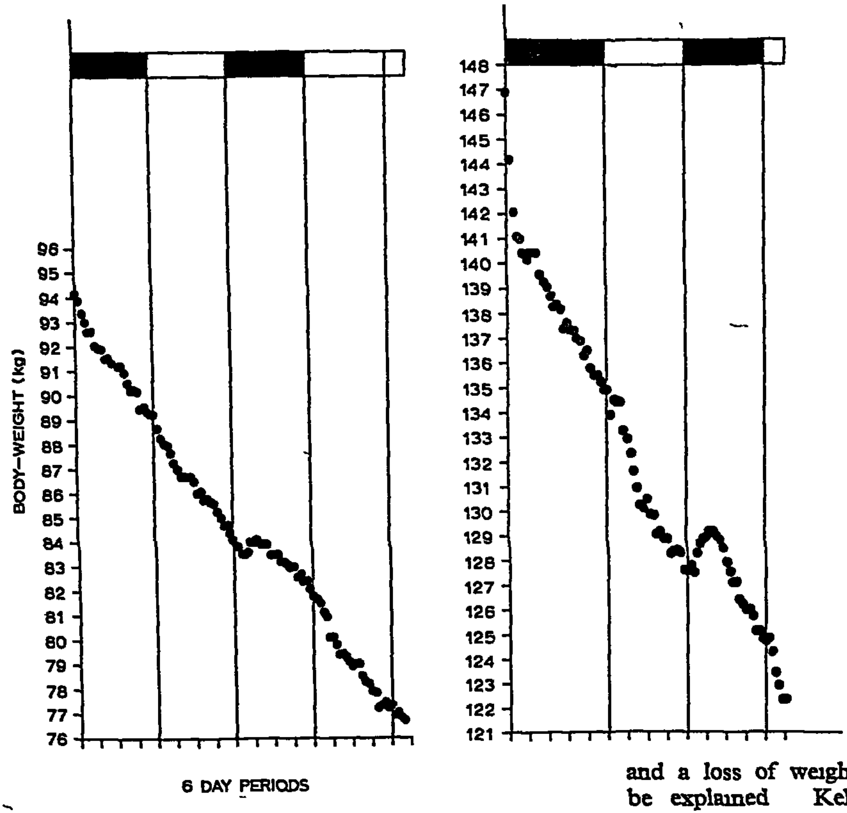
Our results are presented in graphic form (figs 1–9, representing patients 1–9) When the curves are viewed as a whole the constancy of the weight loss is obvious, and the similarity of the results shows that the patients must have been very cooperative There are regular deviations from the main line weight is gained when the diet changes from high-fat to high-carbohydrate, and lost when the



Diet	*Fat*	*Carbohydrate*	*Protein*
Fat	62%	23%	15%
Carbohydrate	9%	78%	13%
Mixed	35%	35%	30%

Salt ad libitum Total water was constant for each patient but varied with each diet.

Figs. 1–4—Experiment I Weight curves of patients 1–4 (800 calories)



Figs 5-6—Experiment II Weight curves of patients 5-6 (1000 calories)

Diet	*Fat*	*Carbohydrate*	*Protein*
Fat	70%	13%	17%
Carbohydrate	8%	75%	17%

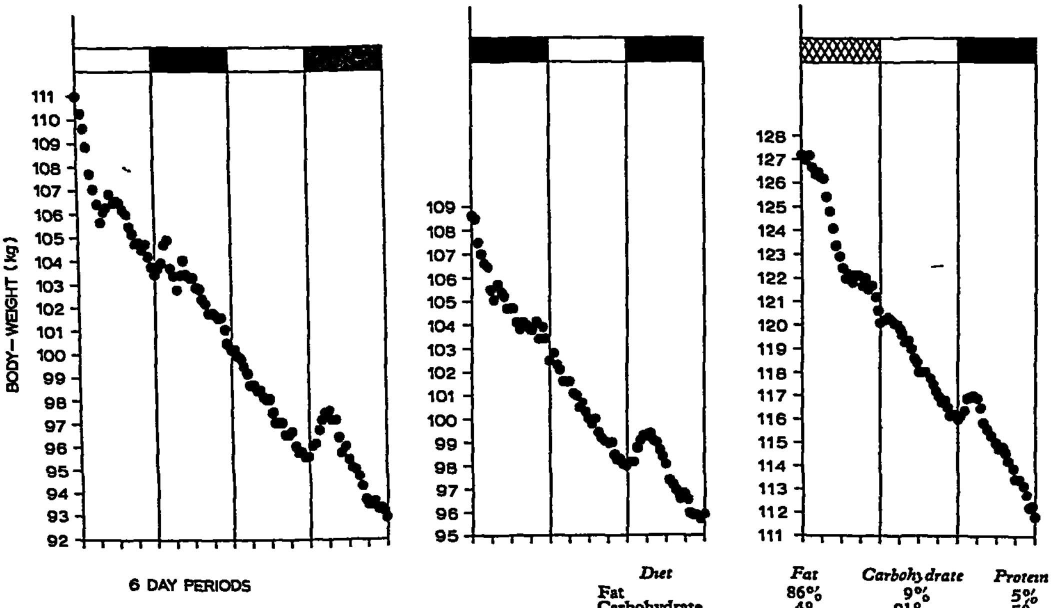
Total water and sodium were constant at chosen level

change is in the reverse direction These " swings " last up to ten days and may amount to 2 5 kg For statistical analysis we therefore only used the part of the curve after the twelfth day on each diet, assuming this to represent a " steady state of weight loss" No significant difference was found in the rates of weight loss, whatever the diet Throughout most experiments the patients were in negative nitrogen balance —more so when on a high-fat diet, when there was also a moderate degree of ketosis The fæcal fat excretion was normal and constant

The 3 patients on the 85%-fat diet complained of tiredness and nausea towards the end of each period On the 91%-carbohydrate diet, they said that they felt invigorated but hungry On the other diets opinions varied

Discussion

From this study it may be concluded that, over the periods studied, isocaloric sub-maintenance diets are equally effective in weight reduction whatever their composition The swings about the main weight curve—a gain in weight when high carbohydrate intake succeeds a high fat intake, and a loss of weight on the reverse change—have to be explained Kekwick and Pawan (1956) showed similar swings and attributed them to changes in the metabolic requirements of their patients on different diets, but they produced no evidence of these changes Anderson (1944) attributed them to the different salt contents of his diets, leading to water retention or loss However, we found the changes—as did Kekwick and Pawan (1956)—even when the salt content of the diets was held constant The swings can be explained largely by variations in the fluid balance which we have observed, but the amounts are not large enough to be detected



Figs 7-9—Experiment III. Weight curves of patients 7-9 (1000 calories)

Diet	*Fat*	*Carbohydrate*	*Protein*
Fat	86%	9%	5%
Carbohydrate	4%	91%	5%
Mixed	40%	35%	25%

Total water and sodium were constant at chosen level accurately by measurements of total body water This is the explanation also given by Lyon and Dunlop (1932) Further studies are in progress

Summary

On 800-calorie and 1000-calorie diets very obese patients lose weight steadily over periods of up to four months

If the periods of study are long enough to achieve a " steady state " the rate of weight loss on a diet consisting mainly of fat does not differ significantly from the rate of weight loss on an isocaloric diet consisting mainly of carbohydrate

When these diets are interchanged, deviations from the weight curve occur, lasting up to ten days These can be accounted for mainly by changes in the fluid balance

This work was supported by a research grant from the board of governors of St George's Hospital We are also grateful to Sister B M Jenner and her staff, to the dietitians, Miss F M Simmonds, Miss A Pyper, and Miss V S Hankin, who supervised the study so meticulously, to Mr W H Brough, who prepared our graphs, and lastly to all our patients, without whose cheerful cooperation the investigation could not have been made

Preliminary Communication

MALFORMATION SYNDROME IN MAN ASSOCIATED WITH TRIPLOIDY (69 CHROMOSOMES)

THE importance of chromosomal variations in human pathology has been firmly established in the past two years Fifteen different types are known to us at present Eight have been discovered here[1-4] The aberrations include trisomy, monosomy, and translocations The highest chromosome number was 49, interpreted[4] as a double trisomy with XXY All these numerical variations represent unbalanced karyotypes, probably caused by non-disjunction during oogenesis or spermiogenesis

Polyploidy has been known in plants and lower animals for a long time In natural populations of vertebrates it is probably quite rare, but conclusive cases are known—e g , among amphibia[5] In mammals no conclusive post-term individuals have been found, but polyploid early embryos are known in rabbits and mice[6]

The discovery of the first individual of the human species with triploid cells is of considerable interest from many viewpoints It should, however, be remembered that this individual was found among a series of patients selected for chromosome studies The condition with which the triploidy is associated may be accidental or peculiar to this particular individual At this juncture and in this short note it can only be said that the findings have many important medical and genetical implications which we intend to consider fully in a later publication

The patient is a boy born on Feb 26, 1959, when his mother was 30 and his father 29 years old Neither his parents (who were unrelated) nor his brother, born in 1957, showed clinical signs of disease or defect

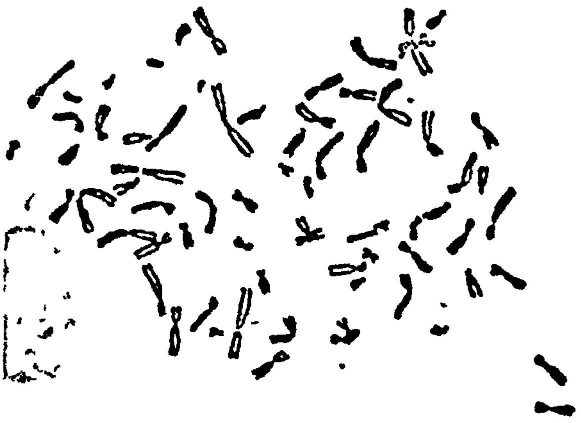

Fig 1—Metaphase with 69 chromosomes

The pregnancy and delivery (breech presentation) were normal Although born at full term, at birth he weighed only 2190 g Malformations were observed at birth His subsequent development was retarded and there were occasional feeding difficulties

The boy was brought to the pædiatric clinic at Örebro on Feb 2, 1960, because of recurrent attacks of fever combined with disturbances of consciousness On examination (Dr Olof Brandberg) he was unable to raise his head when lying flat on his back He showed some interest and played with toys but in general contact was deficient He was small for his age (height 72 cm) He had localised lipomatosis on the back of his hands, feet, and thighs In contrast the lower legs were quite thin His jaws were hypoplastic (micrognathia), and he had cutaneous as well as bony syndactyly of his hands and feet The internal organs appeared normal His genitalia were likewise normal with regard to his size and age Both testes could be felt in the scrotum and had a normal consistence The reflexes were normal, but a peculiar pattern of movements, including some ataxic features, was observed

Radiographic examination —In the skeleton 9 bone nuclei were found instead of the expected 16 No teeth had erupted, but germs were present A pneumoencephalogram showed good filling of the ventricles with no displacement or deformity, but the basal cistern was much dilated, and large air spaces were observed bilaterally over the frontal convexity and parietally on the right side The radiologist's diagnosis was porencephaly

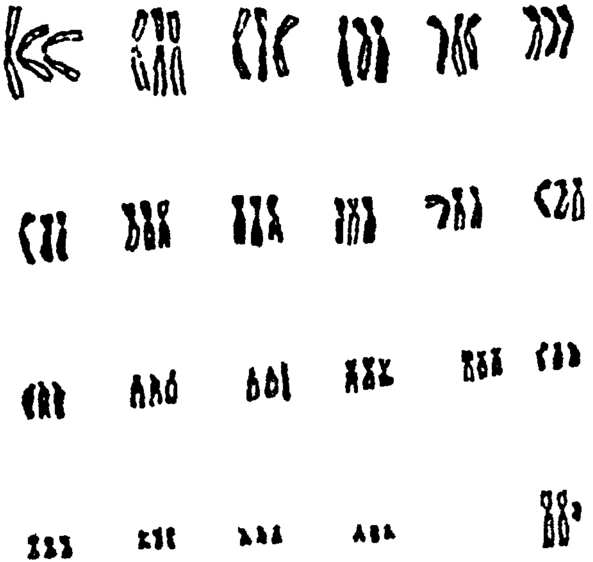

Fig 2—Chromosomes in fig 1 matched to show presence of three haploid sets sex chromosomes interpreted as XXY

[6] Beatty R A Cambridge Monographs on Experimental Biology, 1957, no 7

Laboratory data—Meinicke-Kahn test, dye test (Sabin-Feldman) test, and complement-fixation test for toxoplasma were all negative. Hæmoglobin 88%, red blood-cells 4,400,000 per c.mm , white blood-cells 12,000 per c.mm , erythrocyte-sedimentation rate 13 mm in the first hour (Westergren)

Biopsy specimens were taken from skin Chromosome studies were made according to our standard procedures[7] using the cell-culture technique. In the 11-day-old primary cultures which are the only ones analysed so far, practically all acceptable metaphases (>25) contained 69 chromosomes (fig 1), occasional cells with lower or higher numbers were observed The findings, exemplified in fig 2, indicate the presence of three haploid sets—i e , a chromosome complement of 3A+XXY

For the preliminary clinical information we are obliged to Dr Olof Brandberg, head of the division of Pædiatrics, Örebro Central Hospital

New Inventions

ANAL CANAL SUPPOSITORY

In conjunction with the instrument department and the pharmacy of the Middlesex Hospital, I have devised a simple suppository to reduce the painfulness of certain anal canal conditions Made of suppository base in which is dissolved xylocaine 2% or similar local anæsthetic, the appliance is shaped rather like a chess pawn, with a spherical tip 1 1 cm. in diameter, and a rounded shaft 3 cm. long and 0 9 cm. in diameter, which widens out into a base 2 cm. in diameter It is cast in a modified suppository mould, with braided silk down the centre to prevent breakage (fig. 1)

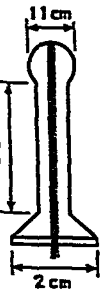

Fig 1

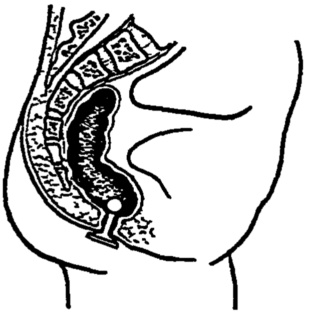

Fig 2

It is simple to use, it should be inserted into the anal canal so that the spherical tip lies above the anorectal ring and the base lies externally (fig 2)

The main advantage of this suppository is that, while melting, it remains within the anal canal by virtue of its shape, thus delivering local anæsthetic in a suitable concentration throughout the anal canal Other suppositories either slip out or slip above the anorectal ring into the ampulla of the rectum. Another advantage is that this suppository can be inserted without the anus being dilated by the finger because its diameter is smaller than that of the finger

Trials in this hospital so far suggest that this suppository is extremely useful in painful fissure-in-ano, giving relief for several hours, and facilitating dilatation It also relieves much of the pain if used before mechanical dilatation and before defæcation in the days following hæmorrhoidectomy It seems to be more effective than systemic analgesics or local anæsthetic jellies

A similar suppository could contain suitable substances—e.g., hydrocortisone, fungicides, or antibiotics—for other conditions of the anal canal.

Reviews of Books

Delinquency and Parental Pathology

Robert G Andry, ph.d , senior clinical psychologist, St. Thomas's Hospital, and lecturer in psychopathology, University of London London Methuen. 1960 Pp 173 30s

The spectre of the incompetent or absent mother hangs over our child-guidance services Counselling sessions between social workers and mothers of disturbed children are apt to be long and dynamic. Father is rarely called in, save as a witness to fact, and his eccentricities are often blamed upon his wife. We have not been alone in calling for[1] a resurrection of the father-image as a matter of importance in any child's upbringing, and Dr Andry has done a service in comparing parental attitude and practice towards 80 thieving and 80 " control " 12–15-year-old lads from working-class London

Maternal identification seemed commoner among delinquents, and environmental communication with both parents, especially father, was poorer When in trouble delinquents consulted their parents less readily than the controls, and while delinquents usually turned to mother, controls turned to father, or to both Mothers of delinquents, however, were more lenient and fathers more emotional in their reactions Breast-feeding lasting over 9 months was significantly more common among controls Delinquents showed the usual preponderance of aggressiveness, resentment, and non-constructive social activity Separation from either or both parents seemed little different in the 2 groups, though, if anything, the fathers of delinquents were absent more often (allegedly due to work)

This study is subject to all the objections that surround retrospective surveys and certainly does not eliminate maternal deprivation as a crucial factor What a delinquent tells the interviewer in a remand home about his father, &c., may be coloured by his cruel fate and by negative transferences towards all the " bad fathers " he has lately encountered. A questionnaire-interview, however well designed, tells us little about the *quality* of a relationship Though delinquents felt themselves loved, particularly by mother, whereas controls nominated both parents, this need not imply (as Dr Andry claims) a causal defect in the delinquent's relationship with father We know far too little from his meagre data of what the mother love means in each case. Nor was there any test-retest, split-half, &c., validation of the methods used in gathering the data, though on some matters the views of parents and child correlated quite well Moreover, exclusion of children with neurotic traits and those from broken homes (we are not told how many were thus rejected) and the smallness of the final sample do not help towards an " over-all " view of delinquency A rather more serious criticism is that all subjects and parents were interviewed in full knowledge of their " delinquent " or " control " status, so that an interviewer's particular bias could have seriously affected the responses The more valid work of the McCords[2] on Massachusetts families suggests that Dr Andry may be overstating his case.

Pending the larger longitudinal study that must one day be done " under the roof ", however, this lucid work is very valuable in helping tentatively to put Father back into the picture, and in emphasising the bonds of love that must exist between a boy and his parent, of whichever sex, if healthy development is to take place

Biochemistry of Blood in Health and Disease

I Newton Kugelmass, m.d , ph.d , sc.d , consultant, Departments of Health and Hospitals, New York Springfield, Ill. Charles C. Thomas. Oxford Blackwell Scientific Publications 1959 Pp 543 126s

The object of this book is " to present the newer knowledge of human blood in health and disease in the light of chemical research, clinical experience and medical necessity " It is arranged in three parts blood in the transport system, blood as the regulating system, and blood as the defence system. The last part rather oddly contains much that is ordinarily classed as "hæmatology", and includes discussion of such subjects as pigment disorders of heme and the hereditary hæmoglobinopathies

---

[1] *Lancet*, 1958, ii, 625

[2] McCord, W , McCord, J., Origins of Crime, New York, 1959

The chapters are packed with solid information, but often collected in an uncritical way For example, a table of distribution of protein components in blood lists, for plasma alone, 11 enzymes, 15 antibodies, 4 coagulants, 3 metalproteins, and 8 lipid complexes, and another table lists 11 causes of hypophosphatæmia and 16 of hyperphosphatæmia There are many informative diagrams reproduced from the work of experts—e g , Hartmann's figure showing the primary areas of disturbance of carbohydrate metabolism, Granick's on the mechanism for iron absorption into a cell of the intestinal mucosa, movement of the iron within the cell, and its delivery into the blood, and one of Owren's most complicated figures on the production and prevention of blood coagulation Then there are many comprehensive tables of quantitative information—for example, the composition and properties of plasma lipoprotein, figures for the acid-base levels of blood at different ages, the blood-copper in 13 diseases, and figures for 60 different chemical components of the erythrocyte (plus 30 components just listed without any figure) The largest table of all is in the appendix, and it gives figures for the normal range of concentrations of over 200 "blood components", including such things as aldolase, diphosphoglycerate P, indican, norepinephrine, pseudoglobulins I and II, and water All this material is listed in an indiscriminating way, but the source is nearly always quoted and this gives some guide to its reliability

Like most compendiums, the book is not meant to be read, but it is a remarkable reference volume to information usually scattered about many monographs For that reason it is well worth having on the library shelf among the biochemical reference books

Stepping Stones to Labour Ward Diagnosis

R H J HAMLIN, M B , M R C O G , formerly medical superintendent, Women's Hospital, Crown Street, Sydney Adelaide Rigby 1959 Pp 160 10*s* 6*d*

IN this small book Dr Hamlin is concerned with the early diagnosis of abnormalities in the first and second stages of labour He has set down, for students, residents, and midwives, the principles which have guided him in his own work in the labour ward His views on the diagnosis and significance of cephalo-pelvic disproportion and of abnormal presentation of the fœtus in labour are supported by diagrams, case-histories, and references to the literature His aims are clear, but the choice of material and the emphasis given to various sections will surprise some readers A great deal is made, for example, of asynclitism, but nothing is said about the diagnosis of breech, brow, or shoulder presentation or of the factors which predispose to these abnormalities Much of the book deals with difficult labour, associated with minor degrees of contracted pelvis, but no reference is made to the fundamental research carried out in Aberdeen since 1947 into the relationship between stature, pelvic shape, and difficult labour Inevitably in a book of this size the teaching tends to be dogmatic—not necessarily a bad feature

Textbook of Toxicology

KENNETH P DUBOIS, M SC , PH D , professor of pharmacology, and director, United States Air Force Radiation Laboratory, University of Chicago, E M K GEILING, PH.D , M.D , Frank P Hixon distinguished service professor emeritus of pharmacology, University of Chicago London and New York Oxford University Press 1959 Pp 302 52*s*

THIS book deals with the pharmacological, clinical, and therapeutic aspects of a number of poisons, including most of the familiar ones and many of the less well-known though contemporary poisons to be found in the home often in a seemingly harmless guise The chapter on household poisons is a miscellany of toxic substances from drugs to cosmetics and crayons Other chapters deal with the poisonous properties of airborne substances (fairly detailed attention being given to toxic dusts), and of metals, corrosives, pesticides, solvents, and other compounds One section is devoted to radiation hazards It is surprising that, among such a number of toxins of which many are not encountered in ordinary medical practice, there is scarcely a mention of aspirin or barbiturates, and neither is included in the list of contents or the index

An account of the historical development of toxicology is an admirable opening chapter of this easily read book, but the details of the medicolegal aspects of toxicology apply to American practice and thus have a limited value outside that country The section on analysis deals with general principles rather than practical instruction, and it may mislead when listing the specimens routinely required for toxicological analysis, for there are several important omissions (blood, for one), and not all forensic specialists would accept the wisdom of preserving organs for analysis in formalin or ethyl alcohol

The Royal Edinburgh Hospital for Sick Children 1860-1960

DOUGLAS GUTHRIE, M D , F R C S E Edinburgh E & S Livingstone 1960 Pp 76 17*s* 6*d*

THIS volume worthily tells the story of the hospital known familiarly and affectionately as "Sick Kids" from its modest beginning a hundred years ago to the present day when it has become one of the leading pædiatric hospitals in the world The author, who has had assistance from seven distinguished contributors, one a Sister and another the Secretary, has illustrated his book lavishly, and the endpaper maps of Edinburgh then and now make the story easy to follow Great names fill the pages and there are some excellent biographies

Prof R W B Ellis contributes a challenging chapter on recent developments These have been accomplished only by using endowment funds And there is this warning "The Hospital cannot hope to retain its proper status—either in teaching, research or service to the community—unless Regional Boards recognise and fulfil their special obligations to the teaching hospitals as spearheads of progress requiring more than the basic necessities for routine hospital service In planning for the future full recognition must be given to the part which the hospital can and should play in improving child health throughout the world" There is a lively and most interesting chapter on Matrons and Nurses There were difficulties in the early years "A wage of £14 a year, the obligation to clean and scrub the wards in addition to extensive nursing duties, beer only when cold beef was served for dinner" made it hard to enlist suitable nurses Anyone connected with or interested in the hospital will treasure this book

---

Recent Advances in Surgery (5th ed London J & A Churchill 1960 Pp 500 60*s*) —In keeping with the notable advances in surgery in the past five years the whole book has been rewritten, to survey those branches in which important progress has been made, and also to consider what recent innovations may have to offer and review "those subjects of which during recent years it has been possible to obtain a clearer picture of what may be expected from well-tried techniques if properly applied " In these objects the editor, Mr Selwyn Taylor, with the help of 28 contributors, has been notably successful, and he deserves warm congratulations for this outstanding addition to British surgical literature Most of the chapters are concerned with individual conditions or organs, such as hydronephrosis or the parotid gland, but there are more general chapters, such as those on the body fluids and tissue transplantation, which reflect the increasing scope of surgical thought The six chapters dealing with the surgery of the heart and peripheral vascular system are outstanding The book is excellently produced, with an adequate index and a useful list of selected references at the end of each chapter

THE LANCET

LONDON 16 APRIL 1960

The Medical Service Committees

A PATIENT who has a complaint against a practitioner under the National Health Service has three possible remedies The patient (or certain specified persons on his behalf) may complain to the appropriate service committee on the ground that there has been a breach of the terms of service—which include, in the case of doctors, requirements as to "proper and necessary treatment". If the complaint is substantiated there will be a report to the executive council, which may recommend "disciplinary" action against the practitioner, but the patient will not obtain redress in the form of damages If, however, the complaint is of professional negligence, the patient can sue for damages in the courts of law. And in certain cases he may be justified in complaining to the General Medical Council, though here again he will not obtain any redress for himself

Is the system of hearing complaints by a service committee fair and reasonable? In their evidence to the Committee on Administrative Tribunals and Enquiries (the Franks Committee)[1] the Ministry of Health and the British Medical Association both defended it on the ground that it has worked satisfactorily and that it has the general consent of the professions concerned Other witnesses, however, were strongly critical, principally on the ground that the numerous stages involve delay and—significantly—that the scales are weighted in favour of the practitioner Nevertheless, some practitioners feel that the system is indefensible. In a letter which we publish in this issue Dr WHEATLEY describes it as "a humiliating and time-wasting procedure" in which the scales are weighted heavily against the doctor from the start, and he would apparently limit the right of complaint to the ordinary remedies of action in the courts or before the General Medical Council.

The difficulty here is that the legal relation between an N.H S practitioner and his patient is not the same as that between other professional men and their clients In the latter case there is a contract between the professional and his client, and a dissatisfied client can withhold his fees, leaving the other party to take the matter to the courts if he wishes The N H S practitioner's fees are paid by the State and his contract is with the executive council—not with the patient. If there is a complaint against a practitioner, it ought to be reported and investigated on behalf of the executive council Indeed, as the Franks Committee pointed out, the whole system is intended to uphold the efficiency of the health service "The ultimate decision which can arise is whether a practitioner should be retained in the National Health Service or not, and the decision here must turn upon his general professional skill and behaviour as indicated by the evidence in one or more individual cases brought to the notice of the deciding authority" That is hardly the kind of decision which should be left to the courts

There may well be scope, however, for improving the system Some regard it as a defect that neither the practitioner nor the patient is entitled to be represented by counsel or solicitor at the hearing before the service committee, although legal representation is permitted at hearings on appeal to the Minister or the N.H S tribunal Some of the issues involved are well reviewed in the Franks Committee report

> "The importance which we attach to the proper finding of the facts at the first stage would seem in itself to be sufficient justification for introducing a right to legal representation It can also be said that the present ban of legal representation operates to the advantage of practitioners since practitioners are often represented before Service Committees by experienced representatives of their professional organisations On the other hand it can be argued that the removal of the ban would also operate to the advantage of practitioners, since they and their representative organisations have greater resources and more at stake than the individual complainant and would therefore more often exercise the right to legal representation. Moreover, a complainant may be said to be acting to some extent in the general public interest, and it is arguable that he should not in so doing have to incur legal expenses."

These considerations led the Franks Committee to recommend that complainants should be assisted from official sources At present there seems little likelihood that this will be done, and it might therefore be better to grant a straightforward right of legal representation to those who care to exercise it.

Some insist that further issues are at stake. In a discussion by the Middlesex Executive Council, Dr R. B L RIDGE described how, in a High Court case in which he had been involved, counsel had torn his opponent's case into pieces "I came to the conclusion I would never agree to any patient of mine, no matter what sort of charge he might make against me at a service committee, to suffer such a soul destroying attack at the hands of counsel".[2] Sometimes, of course, discovering the truth must involve a searching cross-examination in which the evidence of a witness may be torn to pieces But this does not necessarily involve bullying a witness, and if counsel occasionally goes over the borderline of what is reasonable or legitimate, the judge or opposing counsel can always intervene. Provided the chairman exercises proper control, there is no reason why anyone should suffer from the presence of lawyers at hearings before a service committee, and the quality of the hearing might well be improved.

Commentary on the Cardia

INTEREST in œsophageal sphincter mechanism[1] continues, and evidence is accumulating that an intrinsic mechanism not only is present but is effective rather than vestigial INGRAM et al[2] have undertaken experiments to prove the efficacy in dogs of a sphincter vis-à-vis external mechanisms After transection of the œsophagus 3 cm above its termination and conversion of the distal portion into a blind pouch replaced into the thorax through the diaphragmatic aponeurosis, no œsophagitis developed in the pouch transplanted with the sphincter intact (care was taken not to damage the vagus), but inflammation and ulceration developed in the proximal œsophagus anastomosed to the stomach through the normal hiatus, and thus dependent on external mechanisms only for its protection against reflux The œsophagitis thus induced subsided once the normal anatomy was restored by bringing the lower end, and thus the internal sphincter, into circuit again When the lower segment was retained as a blind pouch but invaginated into the stomach, and so bathed in gastric juice while robbed of sphincteric protection, ulceration again developed

Here is incontrovertible evidence of a functioning sphincter in a pronograde animal A bat hanging upside down presumably has even greater need, and that this need is provided for has been demonstrated by BOTHA,[3] who dissected a wide number of species from a dogfish to a tortoise and demonstrated a considerable variation in situation, size, and type according to species BOTHA found no sphincter in the pronograde dog, cat, ferret, and monkey But the presence or absence of a sphincter *mechanism* cannot be established on the anatomical findings alone the experiments of INGRAM et al revealed an intrinsic sphincter mechanism in the dog, in which BOTHA's dissections failed to reveal any intrinsic sphincter The smooth circular muscle-fibres at the lower end, whether or not in greater bulk than elsewhere in the œsophagus, presumably act as a sphincter in relation to the fibres at a higher level Perhaps man, in the orthograde position, hardly needs a strong sphincter, but, as recent investigations have shown,[4] an internal sphincter mechanism cannot be discounted because there is little to be seen in the way of a sphincter Dr GOLDBERG, whose report we published last month,[5] has carried understanding a little further by the neat and simple expedient of radiographic assessment during operative repair By barium studies he showed in patients with hiatal hernia that, though clearance of the hiatus and removal of the hiatal hernial sac does not stop reflux into the œsophagus, approximation of fundus to œsophagus by a few stitches does, since this distributes the gastric pressure over the fundal wall, with a more obtuse cardio-œsophageal angle the sphincter receives and is overcome by the full pressure of a force directed upwards into the fundus, which in this position acts as an aditus or funnel directing the pressure against the sphincter instead of taking the strain from it ZDANSKY[6] has stressed loss of fixation of the gastric fundus in the subphrenic space as an important element in reflux, this displacement leads to alteration of the cardio-œsophageal angle[7] The value of GOLDBERG's observations lies in the radiological proof that simple restoration of acute angulation is effective in man ATKINSON,[8] in a study of 18 patients who had undergone cardiomyotomy, showed that impairment of the sphincter mechanism was greater in those with than in those without postoperative reflux, but in 3, even though no sphincter mechanism could be demonstrated, symptoms of reflux did not develop—perhaps because the angle remained acute enough for the fundus to retain its function as a shock-absorber

The Right Help in the Right Place

OUR social services have developed rapidly since the war, but justifiable pride in them must not turn into complacency For some people still lack adequate and timely support, as may be seen from the following reports from the daily press

> An epileptic, who was expecting her third child in three months' time, appeared before a magistrate's bench on a charge of stealing She had to be repeatedly remanded to prison because she had nowhere to go Four epileptic colonies refused to take her because she was pregnant, while a "mother-and-baby" home refused to take her because she was an epileptic[9]
>
> Four sisters, the eldest aged 6, died in a fire in their home which was a converted bus on an unlicensed caravan site There was no fire-extinguisher on the site and only one standpipe for water Their parents, who had a family of six children, had been evicted from a council house[10]
>
> A family of ten, including eight children aged between 11 years and 18 months, were found living in a disused chalet, 10 ft by 8 ft The mother was expecting another child There were neither blankets nor heating and the household goods consisted of two beds, two mattresses, and a hurricane lamp[11]

These families all came to public notice when a crisis in their lives brought the parents before magistrates or coroner Despite our social services, each had already been living for some time in unsuitable or even dangerous conditions, and the reader is left with the uneasy feeling that other needy pre-crisis families are also struggling without effective help

This unhappy hypothesis is confirmed by Mrs AUDREY HARVEY's experience in a citizens' advice bureau in one of the poorest districts in London, where for five years she has been helping working-class people with their difficulties and questions In a Fabian tract[12] she discusses how and where the social services still fail the sizeable minority who have less money, education, living space, opportunity, and status than the rest of us In another Fabian tract[13] Prof R. M. TITMUSS has reiterated his view that the better-off third of the population enjoy fiscal and occupational benefits at the expense of the welfare services which could offer real support to those who are "living precariously close to the margin of poverty". Mrs HARVEY agrees with this: indeed in her view it is chiefly the middle classes who have benefited from some recent developments of the social services, notably the National Health Service. In unfair contrast, the poor carry a burden of indirect taxation which for them is relatively heavier than for the better-off. Though widows, old people, and the sick are eligible for benefits, these are modest and the regulations hedging extra earnings and National Assistance are, in Mrs HARVEY's view, irksome and often harsh.

[12] *Casualties of the Welfare State* 1960 Pp 32 (2s 8d post free from the Fabian Society, 11, Dartmouth Street London S W 1)

The most urgent basic need of the poor, she thinks, is cheap housing. Yet local-authority building fell from 200,000 dwellings in 1954 to 113,000 in 1958 (though over the same years private building expanded). The "general need" housing subsidy, abolished in 1956, has never been restored, and she says that we spend a lower proportion of our income on housing than all but three of fifteen other European countries. It is a commonplace that the home is the centre of family life, and for a family of wavering stability it may make all the difference between independence and reluctant reliance on the social services. Each of the three examples we cited above had failed to find reasonable accommodation, and a section of Mrs HARVEY's tract describes in detail the misfortunes of a family which almost disintegrated, largely from lack of a home of their own. Though they were given a great deal of expensive help from various social services, no authority seemed able to provide them with the house or flat which at much less cost would have set them on their feet again. "It is one of the salient anomalies of the Welfare State", she writes, "that despite its insistence on 'the importance of the family', far more services are provided for efficiently sweeping under the carpet the remains of a family after it has disintegrated than for preventing this disaster. Nor is it generally recognised that what is needed to prevent this is far less often solemn amateur psychiatry than helpful information and advice and, sometimes—in an emergency—just plain cash as a loan." This last sentence expresses Mrs HARVEY's dissatisfaction with the manners as well as the matter of the Welfare State. In her work at a citizens' advice bureau in a poor district, she has perhaps tended to meet an undue proportion of those who have found its administration bewildering and its help grudging. Standing outside the official specialist services as she does, she has come to regard the professional social worker with some reserve. Though she recognises many notable exceptions, she finds among them a "terrifying tendency to blame unfortunate people for their misfortunes" and to expect of them standards of conformity and virtue "stern beyond belief". To those who see the work of the social services as a whole such criticism may itself seem unduly stern, but at a time when the Younghusband report has set us thinking about the organisation of the social services, her plea for a reconsideration of their purpose and deployment should not be neglected.

Annotations

APPEAL FROM GREAT ORMOND STREET

THE Institute of Child Health, which was formed in 1946 and is associated with the world-famous Hospital for Sick Children in Great Ormond Street, London, has established itself not only as a national but also as an international centre. Most would agree that such a Mecca within each specialty is a necessity—for teaching postgraduates at all levels, for coordinating the study of special problems, and, above all, for research. And in the 1960s even Mecca must be up to date and look to the future.

The Institute has now reached the point where its resources are exhausted and it can neither accommodate all its would-be students nor properly fulfil its research projects. Those who study there can see all types of disease, and, for comparison, the relatively healthy children who attend the Province of Natal Welfare Centre. But the amenities for students are meagre, and the laboratory facilities are badly overcrowded. Such a situation must obviously be remedied quickly at a time when progress in medicine lies so largely in the laboratory. This is perhaps particularly true of pædiatrics, and of advances in the treatment of the sick newborn baby.

Because of the Institute's insufficient buildings and the growing demands made on it as a Commonwealth centre, a new and larger building has become a matter of urgency. A site is available, and plans are already drawn up, but though these include only provisions for the foreseeable future the estimated cost will be £400,000. As part of the British Postgraduate Medical Federation, the Institute would normally look to the University of London for funds from the allocation made by the University Grants Committee. But at present the universities are giving priority to expansion in technology and pure science, and the necessary money is unlikely to be given to the Institute quickly. Accordingly it has launched its own building appeal, in the hope that those who have benefited from the work of "Great Ormond Street", either directly or indirectly, and who believe that its future should match its past, will give all the support they can.

Donations may be sent to Sir Hugh Beaver at the Appeal Office, Institute of Child Health, Great Ormond Street, London, W.C.1.

PREVENTION OF SERUM HEPATITIS

SERUM hepatitis is potentially fatal, and every effort must be made to screen donor blood for the hepatitis virus. In the absence of specific means of identifying the agent or its antibodies, present screening methods are necessarily crude. Donors with a previous history of jaundice are unacceptable, but this does not exclude the significant number carrying the virus from a latent or anicteric form of the disease. In order to detect this group of hepatitis carriers, donor blood has been subjected to a battery of liver-function tests, but none has proved effective.[1,2]

Since serum-glutamic-oxalacetic-transaminase (S G O T) activity was introduced as a sensitive index of hepatocellular necrosis,[3] this has naturally been studied as a possible screening-test to eliminate carriers of hepatitis virus All donor bloods received in the blood-bank of the Memorial Center, New York, in 1956 were examined for S G O T activity [4] The blood was infused before the results of these determinations were known, but from a subsequent follow-up the incidence of hepatitis in recipients was related to the S G O T activity of the blood they had received Of 1371 adequately followed-up recipients, 603 patients received normal blood and 768 received blood with raised S G O T activity Of the 1371 recipients, 39 developed hepatitis The incidence of serum hepatitis was 1 5% among recipients of blood with normal S G O T activity, but 5 5% among those who received blood with S G O T values above 100 units Since the differences were statistically significant it appeared that S G O T determinations would help in excluding hepatitis carriers among prospective blood-donors

In order to arrive at these figures, it had been necessary to determine the S G O T activity of over 13,000 donor bloods, for many unpredictable variables marred the follow-up and final analysis Nevertheless, these results, together with similar studies from other centres, should help to determine whether S G O T activity should be accepted as a standard screening measure in blood-banks in order to reduce the incidence of post-transfusion serum hepatitis

DESENSITISATION IN HAY-FEVER

WHEN hay-fever is caused by grass pollen, desensitisation is ideally carried out with extracts of the particular pollen responsible for the trouble But identifying the culprit is tedious, and as most English grass pollens are antigenically similar, some workers consider it enough to use extracts of random pollens [5–8] Others believe that this practice is more convenient than effective,[9 10] and Feinberg [11] now reports the results of investigations which support this view

Feinberg studied the antigenic relationships between the pollens of 11 common English grasses by refined immuno-diffusion techniques in agar-gel plates He found that, although the so-called " common " antigen of one pollen would react with the antiserum of a different pollen, it did not react completely, each pollen had one or more specific antigens Thus, while desensitisation with a heterospecific pollen could be expected to produce blocking antibodies to related antigens in the causal pollen and might give some relief, it would not produce the full complement of antibodies and so might fail to give complete relief

If symptoms are the result of sensitisation to an antigen specific to the causal pollen, desensitisation with a heterospecific pollen will, of course, fail to give any relief at all When sensitivity to grass pollen is suspected, skin testing with individual pollens should indicate the causal one, for, as only this will contain antigens corresponding to all the antibodies present, it should produce the most intense reaction, and Feinberg maintains that identification in this way of the pollen actually responsible for the trouble is an essential preliminary to rational therapy

Clinical investigation of this matter is obviously desirable, for desensitisation treatment is so tedious that it would be a pity to employ any method but the best

SUBDURAL HYGROMA

SUBDURAL effusions of clear fluid containing no blood were formerly regarded as of the same nature as liquid hæmatomas and were thought to be usually traumatic Admixture of cerebrospinal fluid was ascribed to a tear in the arachnoid [1], and the occasional demonstration of a communication by pneumoencephalography, and the frequency of signs of meningeal irritation, were held to support this hypothesis Recent work has rendered this view untenable and has even cast doubt on whether such cases are ever traumatic in the sense that was originally meant It was realised that such effusions might occur not only in meningitis [2] but also in other diseases not obviously accompanied by intracranial changes,[3–5] such as respiratory or intestinal infection or simple malnutrition Suckling and Wittmann [6] have reported nine cases of coloured children in whom subdural effusion complicated respiratory infections such as tracheobronchitis and pneumonia They conclude that, although hæmorrhage is not certainly an essential precursor, it is difficult to understand how else the exudation is caused

The dural membrane has a capillary bed and is therefore capable of exudation in its own right The arachnoid strictly has no capillary bed, though the pial vessels can exude blood or protein under pathological conditions, and pia is not easily distinguished from arachnoid at every site Suckling and Wittmann report that in all their cases yellow fluid was obtained at the first tap, and that in the majority the fluid contained no obvious blood No case of subdural effusion in whooping-cough has come to light, so the stress of coughing is unlikely to be a crucial factor A positive Wassermann reaction is rare, while the sagittal sinus, whenever it has been investigated, has been patent It has been objected that, if the effusion is aspirated first, the needle may have caused any tear revealed by subsequent pneumoencephalography, while pneumoencephalography may in turn lead to a subdural effusion [7] Certainly, if a brain cannula is passed into an atrophic cerebral hemisphere, the arachnoid is breached, and this may be followed by a typical yellow, proteinous " effusion " in the subdural space The factors here are a brain too small for the skull and a hole in the arachnoid membrane

Fresh light is thrown on the mystery by the investigations of Hill et al [8] into the levels of different proteins in cerebrospinal fluid They conclude that these consist of a mixture of two distinct groups one, characteristic of ventricular fluid, contains prealbumin, and probably results from some active process in tissue of the central nervous system, the other accumulates in the subarachnoid space on the basis of physicochemical properties such as molecular weight and a gradient between the concentration in serum and in cerebrospinal fluid The proteins in the fluid from clear subdural effusion (hygroma) contain the component characteristic of cerebrospinal fluid—prealbumin—whereas those from subdural hæmatoma do not This indicates that the proteins of a hygroma are derived from cerebrospinal fluid The fact that they are concentrated suggests that, whereas the proteins cannot be absorbed from the subdural space, water can Only two such cases have been investigated, and it is not established that all subdural hygromas are of the same nature, but already it is clear that some, if not all, examples of subdural hygroma constitute a separate disease from subdural hæmatoma, though both may share one predisposing factor—namely, a tendency for the brain to fall away from the skull by reason of discrepancy in size In hygroma this factor is particularly evident in children in subdural hæmatoma it is more prominent at the other extreme of age

In all the cases described by Suckling and Wittmann the condition cleared up with repeated aspiration In view of the recent discoveries, stripping of the inner membrane is unlikely to be of much value in treatment

GROWING UP IN NEWCASTLE UPON TYNE

AFTER the late war Sir James Spence inaugurated a new type of sociomedical investigation in child health with the object of examining many unsolved problems Accordingly, a longitudinal study of the health and illnesses of all children born in Newcastle upon Tyne in the months of May and June, 1947, was launched, with the intention of pursuing it up to school-leaving age at 15 years The number of infants enrolled was 1142, but the study embraced many times this number, for it inevitably became concerned with the families of all of them, since the child had always to be considered in his family context Hence the investigation became generally known as the Thousand Family Survey The success of such a project depends very largely on the cooperation and goodwill of all concerned, and the maintenance of these fine qualities by the parents, the family doctors, the staff of the city health department, and the staff of the university department of child health is clearly demonstrated by the continued participation of all but 7 of the original families still living in the area

The account[1] of the investigation covering the first year of life aroused much interest, for it oriented the infant " within the family " and viewed various aspects of infancy from a new angle Further unfolding of this fascinating continuing study of childhood has been eagerly awaited, and the second volume,[2] which has just appeared, covering the first five years of life, will be widely welcomed The first part is concerned with the varying fortunes of the families during the five years, set against the social and economic background of Newcastle, and the second measures the child's environment in terms of housing, family, and medical care The third part contains detailed accounts of illness and is arranged to show how diseases fall into new and more relevant groups when viewed in the family context Part 4 is an estimate of the incidence of illness and defects in pre-school children in Newcastle based on the facts of the survey, and concludes with suggestions for further improvement in the health and wellbeing of children

There was an average of 10 significant episodes of illness, excluding minor colds, minor skin sepsis, and herpes labialis, in each child in the first five years, 80% being infective illness and 20% non-infective Respiratory infections including whooping-cough accounted for nearly two-thirds of the infective illnesses, followed by acute infectious fevers (15%) and alimentary infections (11%), these three together accounting for 87% of infective illnesses Staphylococcal infections occurred in 5%, and 3% had acute infections of unknown origin Nearly all the fatal infections were in the first year, as were nearly all the other serious infections apart from pneumonia Nearly half of the 20% of illnesses which were non-infective were accidents, but few of these happened in the first year before the attainment of mobility Developmental conditions, such as speech defects and non-infective skin rashes, accounted for most of the remainder

The environment of the survey children was considered to be wholly satisfactory in only 47% and lacking in one or more respects in 53% On more detailed analysis there was some deprivation of parental care, such as marital instability or mother working full-time, in 45%, some deficiency of maternal care such as defective diet, clothing, or supervision in 16%, and some social dependence, such as unemployment, in 20% All three of these unsatisfactory features were present in 8% This is a rather depressing picture of family life, but, after all, these children were viewed against a background of perfection and most of the imperfections noted, however regrettable, were not serious Nevertheless, it is rightly claimed that social measurements along such lines are essential for a sound understanding of illness in childhood as well as for rational prevention and treatment For instance, such a social diagnosis is particularly important in respiratory and alimentary infections, accidents, and enuresis

Throughout the five years there was no significant relationship between the frequency of calling the family doctor and the Registrar-General's social class or the standard of the mother's care The family doctor was called to 58% of the illnesses, the figure being approximately the same before and after the introduction of the National Health Service Children were referred to hospital outpatient departments by family doctors for 17% of illnesses (25% in the first year) and they were admitted to hospital for 5% (11% in the first year) Doctors were much more likely to be called for some illnesses than for others They were usually called for pneumonia and for illnesses with a rash, but in only half the cases of suppurative otitis media and accident. In the five years only 11 of the 847 children (1 2%) did not receive medical attention at all

In the five years 56% of the children attended a hospital outpatient department at least once, the attendances being more frequent in the first two years 90% of the attendances were accounted for by accidents, infections, and questions concerning circumcision and tonsillectomy 20% of the children were admitted to hospital at least once in the five years Infective illness accounted for 59% of admissions in the first year, 64% in the second, and 50% in the third, but after the third year there were few for infections and many more for surgical procedures—especially tonsillectomy Though numerous in the outpatient department, accident cases seldom required admission

---

[1] Spence, J , Walton, W S , Miller, F J W , Court, S D M A Thousand Families in Newcastle upon Tyne London, 1954 See *Lancet*, 1954, ii, 371

[2] Growing Up in Newcastle upon Tyne By F J W MILLER, S D M COURT, W S WALTON, and E G KNOX London Oxford University Press (for the Nuffield Foundation) 1960 Pp 369 25*s*

The acute infectious diseases of childhood were found to be largely independent of social class or family environment, but such was not the case in the important and more serious group of endemic family infections—notably staphylococcal infections, streptococcal infections, tuberculosis, herpes simplex, and infestation with scabies and head lice These infections tend to involve the family as a whole They can become established within the family, producing isolated or recurrent acute episodes or chronic illnesses over a long period, and the expression of the infection varies with the age of the individual

The observations on the development and disorders of speech are of particular interest A third of the children passed through a period when articulation was so defective that speech was unintelligible At 5 years, however, 94% had intelligible and fluent speech, while 5% had unintelligible speech and 1% delayed development of language 37 developed a stammer but in only 1 did it persist beyond the age of 5

The third and final report covering the school-age period of 5 to 15 years will complete this valuable study, which has already illumined many aspects of child and family life that had long been neglected, but it cannot appear for several years because the children concerned will not reach the age of 15 until the early summer of 1962

AGE CHANGES IN HUMAN CARTILAGE

HYALINE cartilage has many of the properties of the ideal supporting material for the correction of contour defects by reconstructive surgery It is used quite extensively for this purpose, but unfortunately the heterogeneous material is often absorbed or replaced by fibrous tissue with loss of its supporting effect Since the supply of autogenous material is limited, and its provision may be prohibited for other reasons, the suitability of homologous cartilage is being investigated [1]

As an essential preliminary, Hagerty et al [1] have studied metabolic aspects of human cartilage, its viability, and its changes on storage and after implantation into volunteers By counting the cells capable of taking up neutral-red from a dilute solution in Tyrode's fluid, they showed that in specimens removed at necropsy from young adults about 98% of the cells were still viable With increasing age of the subject, however, there is a sharp fall in the number of cells per unit area The fall with increasing life-span in the metabolic activity of cartilage, measured by its anaerobic glycolysis, was found to correspond to the fall in cell-count This indicates that the metabolic activity of the individual cartilage cells changes little with age, the measured decline resulting entirely from the reduced number of cells The observed fall in potassium also corresponded to this decline in the cell population Sodium, however, is mainly extracellular and its considerable loss from the cartilage of older subjects is due largely to the progressive dehydration of ageing By using the potassium content to calculate the volume of the intracellular-fluid compartment, and hence by difference that of the extracellular compartment, Hagerty et al showed that the loss of sodium with age between 14 and 60 years exceeded by some 21 mEq per kg of fresh material that which could be accounted for by the simple reduction in extracellular fluid The excess must, therefore, have come from the bound sodium, which at the younger age amounts to over 100 mEq per kg of fresh material This loss of bound sodium could be due either to replacement by calcium or to loss of base binding material from the intercellular ground substance The fall in chondroitin sulphate with age [2, 3] is no doubt mainly responsible for the observed fall in bound sodium, and this fall in chondroitin sulphate is itself probably the consequence of the pronounced decline in the cell population

To what extent these various age changes affect the suitability of cartilage for reconstructive surgery may be shown by the studies on implants into volunteers In homologous transplants of other tissues viable cells rapidly disappear With cartilage, however, both histological [4] and metabolic [5] studies suggest that the majority of the transplanted cells survive indefinitely With human cartilage stored in human plasma at 4°C, Hagerty et al [6] have found that the viability of the chondrocytes falls to zero after 50 days, but that after 25 days about a third of the cells are still alive Implants of such cartilage into volunteers for periods ranging from 134 to 1059 days still contained, on removal, an average of 33% of viable cells Moreover the superiority of these implants over those in which all the cells had been killed by storage in merthiolate saline was clearly shown by the reduction, by a factor of two-thirds, in the degree of fibrous invasion In view of these encouraging results, further efforts will no doubt be made to improve the viability of the cells on storage

SENSITIVITY OF GONOCOCCI TO ANTIBIOTICS

STUDIES by Finland and his colleagues in 1950 [7] and again in 1955 [8] failed to reveal any important increase in resistance of gonococci to penicillin or other antibiotics It was also found that fewer strains were resistant to sulphadiazine in 1953–54 than in 1949 Hirsch and Finland [9] have now investigated the susceptibility to penicillin and twenty other antibiotics and to sulphadiazine of strains of gonococci isolated late in 1958 and early in 1959 from cases of acute urethritis in males

Each of the agents, except penicillin and sulphadiazine, inhibited all the strains tested within a fairly narrow range of concentrations Penicillin, erythromycin, and the tetracyclines were the most active of the commonly used agents, whereas polymixin and colimycin were the least active, weight for weight Hirsch and Finland remark that in-vitro sensitivity by itself is no reliable guide to effectiveness in vivo Other important factors include the absorption, distribution, and excretion of the drug—and particularly its concentration in the urine and its capacity to penetrate into infected areas Few, if any, of the antibiotics can be expected to act on intracellular organisms, and secondary infection, particularly with penicillinase-producing staphylococci, may be the cause of some failures with penicillin

---

MR B D FRASER, a deputy secretary in the Ministry of Aviation, is succeeding SIR JOHN HAWTON as permanent secretary of the Ministry of Health Sir John, who has held this appointment since 1951, is giving it up on medical advice but will undertake special duties in the Treasury

THE CONCEPT OF EGG YOLK AS A DIETARY INHIBITOR TO RHEUMATIC SUSCEPTIBILITY

ALVIN F COBURN
M.D
ASSOCIATE PROFESSOR, DEPARTMENT OF PEDIATRICS,
NEW YORK MEDICAL COLLEGE, NEW YORK 29, U S.A.

> "Certainly, if I had to start again the weary struggle with rheumatism, I should have to reconsider my views on nutrition Under-nutrition may be general or special and bids me at the moment tread with caution, for we shall learn much more about this in the future."—F J POYNTON (1938)

THE past two decades have seen the establishment of the hæmolytic streptococcus as the factor of infection in the rheumatic state (Coburn 1931) and the prevention of rheumatic recurrences by antibacterial prophylaxis (Coburn and Moore 1939, Thomas and France 1939, Rammelkamp 1955-56) In sharp contrast to these advances has been the lack of progress in defining the factors which determine rheumatic susceptibility It is generally recognised that rheumatic fever is limited to less than 5% of the population, those with a "diathesis" This appears to be a genetic abnormality, probably manifest in biochemical disturbances for example, a difference in lipid metabolism between rheumatic subjects and their non-rheumatic siblings has been reported (Chang et al 1957) Yet there is no knowledge of dietary needs during infancy and childhood peculiar to the rheumatic subject.

In this paper I recapitulate and discuss observations showing that (a) inadequate nutrition is part of a poor environment, (b) rheumatic-fever children usually lack sufficient eggs in their diets, (c) the escape from poverty is followed by an increase in the consumption of eggs and a decrease in the incidence of rheumatic fever, (d) supplementation of children's diets with egg yolk or certain fractions thereof is followed by decreased rheumatic susceptibility, and (e) there is a fraction of egg yolk which in extremely small amounts has been found to have high antiallergic activity in laboratory animals

Some Effects of Loss of Poverty

In childhood, high morbidity-rates for rheumatic fever are associated with poverty In London, poverty is accompanied by a "bad micro-climate" (Poynton 1938) In New York, the association between home environment[1] and the incidence of rheumatic fever can be clearly envisaged at the intersection of Park Avenue and 96th Street (Coburn 1958) South to 46th Street, both sides of Park Avenue are solidly built with luxurious skyscraper dwellings which house large numbers of children Nowhere in New York City are families more wealthy The northern part of Park Avenue, on the other hand, has for many years been a slum area solidly built with five-storey tenements Whereas rheumatic fever has long been prevalent north of 97th Street, it is rarely seen by pædiatricians practising south of the intersection (Mason 1958)

The present study began in 1947 in Chicago Rheumatic fever was particularly prevalent in the Stockyard area (Bridgeport district) with its population of some 50,000[2] These were families with many children, all Caucasian but of many national backgrounds—Polish, Lithuanian, German, Italian, and so on. Their diets differed according to ethnic background, but up till 1941 they had little money to feed many mouths After world war II their fortunes changed precipitously Not having to pay higher rent at that time, they spent their larger incomes on more and better foods, including luxury items

Since the rheumatic children and their parents were continuously under my care, it was possible to detect most of their streptococcal infections For the purposes of this study non-suppurative infections were treated symptomatically without antibiotics or sulphonamides The expected incidence of group-A streptococcal nasopharyngitis with the serological types prevalent in Chicago did occur in these rheumatic families, but rheumatic recurrences almost disappeared By 1955, after several years without recurrences, there seemed to be no further need for this rheumatic-fever clinic. The most striking fact in the five years before the clinic was closed was the disappearance of initial rheumatic attacks I did not see a single new case of rheumatic fever among the hundred rheumatic families under observation, even though a large number of younger siblings contracted streptococcal infections This raised the question Had group-A streptococcus lost its "rheumatogenicity" or had some environmental factor associated with the large rise of income modified host reactivity in a way that made the children less susceptible to rheumatic fever?

It so happened that this study was paralleled by a simultaneous survey of rheumatic fever at an all-Negro grade school nearby There, the family income remained extremely low, and the incidence of the disease remained high Likewise, about two miles away, in my rheumatic-fever clinic at the Cook County Hospital, new cases of rheumatic fever became relatively rare in the higher-paid Caucasian groups but did not change in the underprivileged Negro community As a result, by 1954-56, the clinic population was mostly Negro The streptococcus had *not* lost its "rheumatogenicity" among the poor Negro families living in areas near the Caucasian Bridgeport district where poverty had considerably lessened

Although one cannot exclude the importance of unknown environmental changes, it was possible to show what happened to the diets of these children when income increased more rapidly than living costs I limited myself to boys and girls aged 7–15, divided for diet studies into three age-groups, 7–9, 10–12, and 13–15 No data were obtained on infant feeding, though its significance to maturation of the rheumatic process is recognised

---

[1] Breast-feeding of infants has usually accompanied a "bad micro-climate", whereas bottle feeding has become a characteristic of infant feeding where home environment conditions are excellent For example, one pædiatrician with a wealthy Park Avenue private practice below 96th Street reported that breast-feeding was a rarity among his patients in the period 1932–41 (Weisman 1959) Recently it has been pointed out that breast-feeding has for two decades been decreasing among all American mothers, "in America only 1 in 5 has breast-feeding at the end of the lying-in period" (Hytten 1959) Attention is called to this point because of the possibility that infants who are breast fed may have lower blood-lipid levels than those fed with cows' milk (Zarafonetis and Kalas 1958)

[2] A house-to-house survey was made during the summer of 1947, and every family in the Bridgeport district was questioned in its native language. Information was obtained on the incidence of hospitalised cases of rheumatic fever, the accuracy of which was checked by medical personnel Lay volunteer workers from social service agencies obtained collateral information on location at time of first rheumatic attack, income, duration of residence, occupation, size of family, number per room, food preferences, schools attended, and other matters of general public-health interest

TABLE I—VARIATIONS IN DIETARY CONSTITUENTS AMONG 1039 CHILDREN OF DIFFERENT INCOME AND AGE-GROUPS
Percentage Meeting Recommended Allowances *

Group	Ages	No. of children	Eggs †	Milk ‡	Total protein	Animal protein	Vitamin A	Vitamin C
a Grade-school children in poverty	7–9	123	89	19	33	62	6	1
	10–12	155	82	12	17	60	5	10
	13–15	109	90	3	23	44	5	6
b Quiescent rheumatic children in poverty	7–9	49	86	53	53	78	17	24
	10–12	59	85	67	52	79	15	22
	13–15	45	74	19	23	53	11	22
c Non-rheumatic children after 5 or more years at moderate economic level	7–9	169	100	59	68	65	32	71
	10–12	138	100	72	79	71	32	68
	13–15	192	100	37	35	100	33	69

* Requirements for eggs and milk are unknown.
† Percentage receiving any eggs, excluding prepared foods.
‡ Percentage receiving milk, 3 cups ages 7–9, 4 cups ages 10–15.

Dietary information from the rheumatic subjects and their siblings was obtained by three methods.

1. A dietary history was taken at the clinic by skilful interviewers—a nutritionist and a nurse.
2. A food recall method was used by the nutritionist and nurse to determine the previous twenty-four hour intake of foods.
3. A questionnaire booklet was given to families for each child, to cover a seven-day period. In this booklet the food records were maintained by each individual for himself and then checked by interview with the nutritionist and nurse.

For the purpose of this study, the food intakes were tabulated in groups of foods.[3]

The diets were tabulated for servings of milk, including cheese and foods made with milk, meat including fish and fowl, liver, eggs, enriched grains and cereal products, non-enriched grains and cereal products, cakes and cookies, candy bars, legumes, potatoes, fruits and vegetables high in carotene, fruits and vegetables high in ascorbic acid, total servings of fruits and vegetables. Soft drinks, tea or coffee, and medications used as nutritional supplements were listed. The only nutrient which was calculated was protein. Experience of others has shown that an approximation of the protein intake provides a good indication of the adequacy of niacine, thiamine, and iron. Tabulation of the milk intake provides an indication of the calcium and riboflavine content of the diet. Vitamin A, carotene, and vitamin-C contents of the diet were estimated by calculations of fruits, vegetables, and liver.

Three groups of children, divided as to economic and health status, are shown in table I.

Group a are an average grade-school population living in poverty, typical of the Stockyard area of Chicago in 1947.

Group b are quiescent rheumatic children, of the same economic level sharing the "bad micro-climate" of the Bridgeport district. They had attended cardiac-school classes and had had many months' association with doctors, nurses, and dieticians in hospitals and convalescent homes.

Group c are with 2 exceptions, non-rheumatic. The children had "graduated" from low to moderate incomes but still occupied quarters typical of the Bridgeport district. Their families had spent their increased earnings on food rather than on more expensive homes in the suburbs.

With increased income there is a striking rise in the proportion of children receiving adequate amounts of vitamins C and A, total protein, milk, and eggs.[4] In the case of eggs, all children whose families had a marked rise in income (group *c*) ate at least one egg a week, whereas 14–26% of the rheumatic poor children (group *b*), and 10–18% of the unselected poor children (group *a*) had less than one egg a week (table I). Furthermore, when families of children could afford it (group *c*) each child consumed, excluding eggs used in cooking food, between 4·0, 4·1, and 4·7 eggs (mean value) per week in the three age-groups studied.

Children who developed rheumatic fever (group *b*) had better diets, even though their financial condition was unchanged. But, though they got more milk, total protein, animal protein, vitamin A, and vitamin C, they did not get more eggs. For each age-group the consumption of eggs was lower among the rheumatic children than among their schoolmates. This finding is in accord with the observations of Wallis (1954), who pointed out a dislike for eggs in rheumatic-fever subjects.

TABLE II—STATISTICAL ANALYSIS OF DIETS IN THREE GROUPS OF CHILDREN (THREE AGE-GROUPS COMBINED)

—	(*a*) Grade-school children in poverty		(*b*) Quiescent rheumatic children in poverty		(*c*) Non rheumatic children after 5 or more years of relative prosperity	
	Mean	S.D.	Mean	S.D.	Mean	S.D.
Eggs (per week)	3·5	±3·0	2·8	±2·7	4·3	±3·2
Milk (cups per day)	2·0	±0·9	3·1	±1·2	3·6	±1·1
Total protein (g. per day)	62·6	±13·4	69·4	±14·1	73·1	±15·7
Vitamin A	2·7	±2·2	3·6	±2·5	6·0	±3·5
Vitamin C	2·7	±2·5	3·7	±2·8	9·4	±4·3
No. of subjects	387		153		499	

Table II shows the average consumption of each of the five foods in each of the three groups.

After children of poor families (group *a*) had recovered from rheumatic fever (group *b*) their diet was better. Diet also improved when poor families (groups *a* and *b*) emerged from poverty (group *c*).

Whereas the environment was not obviously improved when children with rheumatic fever (group *b*) returned to their homes, there was a statistically significant increase in their consumption of all foods studied, except eggs. Moreover, there was also a statistically significant difference between the low egg consumption of the poor rheumatic children (group *b*) and the relatively high egg consumption of the children of families in moderate financial circumstances (group *c*). The differences in mean consumptions of each food for each pair of groups (group *a* v. group *b*, group *b* v. group *c*, group *a* v. group *c*) were tested statistically. All comparisons were statistically significant at the 1% level ($P < 0.01$) These tests are summarised

---

[3] Wilcox and Galloway (1954) determined food consumption in terms of nutrients as calculated from seven-day records in Utah children. Among these were 131 rheumatic subjects paired with 131 controls of the same economic level. In this study, a statistically lower consumption of calories and five nutrients was found for the rheumatic girls. However, the differences among the boys was not statistically significant. Although the rheumatic group fulfilled the recommendations of Jackson and Kelly (1949) for meat, fish, poultry, and some fruits, this group failed to meet the requirements for milk, eggs, and tomatoes. In contrast to the controls who disliked liver and several other foods, 10% of the rheumatic subjects expressed a dislike for certain vegetables and eggs.

[4] Previous studies indicated that supplementation of diets with other foods had no detectable effect on susceptibility to rheumatic recurrences. Items tested individually for a period of one to three years on rheumatic children were vitamin A, vitamin C, milk, and the protein of egg yolk.

Group *a* v group *b*—The mean consumption of each food (except eggs) is higher for group *a* Egg consumption is significantly lower for group *a*

Group *b* v group *c*—The mean consumption of each food is higher for group *c*

Group *a* v group *c*—The mean consumption of each food is higher for group *c*

Possible Association Between Lack of Eggs in Childhood and Rheumatic Fever

It was seen in table I that 10–18% of Chicago children in poverty (group *a*) had no eggs in their diets except in prepared foods For quiescent rheumatic children, also in poverty (group *b*), the figure was 15–26% The mean values for eggs consumed per week, according to age, for the three groups of children studied are shown in table III The proved rheumatic subjects (group *b*) consumed the least eggs Next in consumption were the underprivileged children (group *a*) In this group the incidence of rheumatic fever was 2.8%, whereas among children of group *c*, who ate the most eggs, it was only 0.6% A survey of group *c* families showed that before the escape from poverty, they had experienced a high incidence of rheumatic fever Group *c* had a familial history of at least 12% among the preceding generation—parents and their siblings It was estimated that during the years 1920–40, when this generation had been underprivileged children, they had had an incidence of rheumatic fever of about 3%

TABLE III—EGG CONSUMPTION BY AGE IN THREE GROUPS OF CHILDREN

Age	No of children	Eggs per week	S.D
Group a			
7–9	123	3·4	±2·8
10–12	155	3·5	±3·0
13–15	109	4·3	±3·1
Group b			
7–9	49	2·8	±2·1
10–12	59	2·7	±2·9
13–15	45	3·0	±3·0
Group c			
7–9	169	4·0	±2·6
10–12	138	4·1	±3·0
13–15	192	4·7	±3·2

The above findings among Chicago pupils are in accord with the possibility that there may be an association between poverty, low consumption of egg yolk during childhood, and maturation of the rheumatic process

Nutritional surveys were also made in New York City before the war The diets of wealthy Brearley School girls, among whom there had been no case of rheumatic fever in ten years, were compared with the diets of poor rheumatic-fever children living near this school. The diets of the Brearley School girls were adequate in all respects, including the daily consumption of eggs, whereas the rheumatic children had multiple dietary deficiencies and few eggs (Coburn and Moore 1943)

Supplementation of Diets with Egg Yolk

Meanwhile, supplementation of diets was tested in small groups of rheumatic children In New York City the supplement was eggs or whole powdered egg yolk, while in Chicago it was fractions of powdered egg yolk.

1 For two years 30 children at a convalescent rheumatic home received four egg yolks daily No other change in diet was made and no antibacterial drugs were given. 22 of these children contracted 24 proved group-A streptococcal infections with many serological types (Coburn 1945), but none showed clinical evidence of rheumatic recurrences This was in sharp contrast to previous experience in the convalescent home, where rheumatic recurrences had been seen each year (Coburn and Pauli 1935)

2 Rheumatic boys and girls living at home in New York City also received food supplements No prophylactic drugs were given, but 60 children had supplements (including eggs) during winter and spring months, while 29 served as "controls" The clinical results were

i Of the 29 children on their normal diet (many deficiencies) 11 had a recurrence

ii Of the 35 children whose normal diet was reinforced daily with two eggs, a quart of milk, meat, butter, halibut-liver oil, 'Viosterol', &c, 3 had a recurrence

iii Of the 25 children whose normal diet was reinforced only with powdered egg yolk (equivalent to six eggs daily), 1 had a recurrence

3 A two-year study was made of the effect of giving egg-yolk powder (equivalent of four egg yolks daily) to rheumatic children for three to four weeks after they developed hæmolytic (group A) streptococcal pharyngitis No medication was given during this period. Of 28 receiving this supplement, only 1 showed fresh rheumatic activity, whereas among 28 "controls" on their normal diets (which had many deficiencies) 10 showed it

4 A one-year study in which about 40 rheumatic children (many dietary deficiencies) received a daily supplement of only the protein fraction from four egg yolks was discontinued because of rheumatic recurrences

5 Finally, in a four-year study made in Chicago in 1952–56, the normal (deficient) diet of 45 rheumatic children was reinforced with egg-yolk alcohol-soluble material (A.S M.) produced by Dr Claire Graham of Wilson Laboratories (Coburn, Graham, and Haninger 1954) No other changes in their inadequate diets were made, no sulphonamides, antibiotics, or other significant drugs were administered. On the average, 35 highly susceptible rheumatic subjects received the supplement throughout the school year, September to July The equivalent of six egg yolks was advised, and about half of this was actually consumed, in the form of an elixir taken twice daily All but one of these rheumatic children were under fifteen years of age

During the four years 45 children, considered highly susceptible rheumatic subjects, were given this material. A minimum of 17 attacks was expected among them after streptococcal infections, but only 5 occurred.

The data obtained under these various conditions, both in New York and a decade later in Chicago, were found to be statistically significant However, from the viewpoint of the statistician, the experimental design was not ideal

Anti-allergic Activity of Egg-yolk Substances

Experimental findings clearly indicate that there is at least one antianaphylactic substance in egg-yolk alcohol-soluble material, which appears to be absent from the protein or acetone-soluble material (Coburn et al 1954) This finding has been confirmed and extended in several laboratories by measuring joint and skin lesions in either the Arthus or tuberculin reaction

French and Allen (1955) showed that the reverse Arthus reaction could be used successfully to demonstrate the anti-inflammatory effects of egg-yolk phospholipid fractions Chang and French (1956) found that the active material was in the A.S.M., absent from the protein and acetone-soluble fractions, and that the anti-inflammatory effect did not appear to be mediated by the adrenals Following the important work of Long and Martin (1956), Kuehl et al (1957) identified in egg yolk N-(2-hydroxyethyl)-palmitamide as a natural occurring anti-inflammatory agent Later, Ganley and his associates (1958) in a wide variety of tests studied the anti-inflammatory activity of compounds obtained from egg yolk, peanut oil, and soybean oil Their crystalline fractions from three sources were all identified as N-(2-hydroxyethyl)-palmitamide They were active (antianaphylactic) at 0.3 μg per kg body-weight.

This work was extended by Ganley and Robinson (1959) Instead of the Arthus reaction (joint swelling) in the guineapig they studied systemic anaphylaxis in the mouse Approximately 50 μg per kg (1 μg per 20 g mouse) gave survival-rates comparable to those obtained after treatment with 100 to 200 mg hydrocortisone per kg body-weight

Discussion

The lack of a suitable experimental animal has prevented direct attack on the factors which determine susceptibility to the rheumatic state The approach has had to be circuitous, by collecting observations on human subjects Among findings made indirectly, one is impressed with the circumstantial evidence that poor nutrition in early childhood may determine whether the genetically susceptible child either escapes or enters the rheumatic state One food, which in the past has been expensive and not consumed abundantly by rheumatic-fever children is egg yolk What metabolic functions are entered by constituents of the egg are unknown Egg yolk is high in phospholipid, its antiallergic activity is in the alcohol-soluble fractions containing lecithin and sphingomyelin (Coburn et al 1954), the blood-level of these two lipids is lower in the rheumatic subject than in non-rheumatic siblings (Appleton et al 1959), as is true also for total lipids, phospholipids and cholesterol (Chang et al 1957)

It is recognised that egg yolk probably has no effect on rheumatic manifestations Furthermore, evidence collected in military and civilian populations suggests that when the host has passed puberty the consumption of egg yolk may not suppress maturation of the rheumatic process Nevertheless, the cumulative evidence does indicate an association between egg consumption *in childhood* and the degree of susceptibility to rheumatic recurrences This evidence is circumstantial There is need for definitive studies of sufficient magnitude and duration—in areas where poverty is great, antibiotics are not available, and streptococcal infections of the upper respiratory tract are prevalent—to provide statistically valid information on whether egg-yolk substances given abundantly in infancy protect against the rheumatic state

The critical problem remains What determines whether the child infected with hæmolytic streptococcus enters the rheumatic state? At this time, the concept that one or more factors in egg yolk may inhibit maturation of the rheumatic process may seem like grasping blindly at a delicate straw But, who would ever have envisaged the beneficence of cowpox?

Summary

1 Most children who developed rheumatic fever before puberty had had inadequate diets in childhood, including a low egg consumption (table I)

2 In the years after they had been in hospital for rheumatic fever, there was a striking increase in their consumption of all foods except eggs Comparing these quiescent rheumatic children with their non-rheumatic siblings, their egg consumption was consistently lower This difference was significant statistically at the 1% level (table II)

3 Also statistically significant ($P < 0.01$) was the higher consumption of egg yolk and other foods in families who had escaped poverty, as compared with rheumatic and non-rheumatic families in poverty

4 General improvement in diet during childhood (other recognised factors of the poor environment being

bidity-rate for rheumatic fever Compared with the underprivileged families from which the rheumatic fever children came, the families which had emerged from poverty had a strikingly lower incidence of rheumatic attacks

5 Throughout these studies the low consumption of eggs seemed to be associated with a high incidence of rheumatic recurrences

6 After the diet had been supplemented with whole egg yolk or the alcohol-soluble fraction thereof, rheumatic recurrences fell below the expected number

7 An antiallergic component of the alcohol-soluble fraction has been isolated, identified, and synthesised Its action in laboratory animals against the immediate and delayed types of hypersensitivity reactions is described

8 The possible effect of egg-yolk ethanolamine palmitamide as a dietary supplement is being tested among children of the poor in New York City

9 The underlying biochemical mechanism of the rheumatic state and its relation to nutrition in infancy remain to be determined

This work was supported by grants from the Easter Seal Research Foundation and the New York State chapter of the Arthritis and Rheumatism Foundation

I am indebted to Mr Herbert Rich, of the New York Medical College, for making the statistical analyses

PRESCRIBING RESTRICTIONS IN AUSTRALIA

FROM AN AUSTRALIAN CORRESPONDENT

THE new Australian pharmaceutical benefit book issued on March 1 demonstrates how quickly a free drug scheme can grow in size and complexity Originally introduced in 1950 as a scheme to supply free a few lifesaving drugs to the general public and a limited formulary to what were then "a few" pensioners, the scheme has rocketed from £3 million to £27 million a year, due to (1) the addition of new costly drugs, such as the oral diuretics and newer antibiotics, and (2) the great increase in the number of pensioners

The object of the amended Health Act which precipitated this new issue was, firstly, to widen the scope of drugs prescribable under this scheme, so that practitioners might be encouraged to return to using the cheaper forms of drugs listed in the B P, and, secondly, by imposing a 5s fee on all scripts except pensioners' to recoup some loss and deter unnecessary prescribing

The book is divided into several sections The first gives 62 administrative clauses, the second a schedule of ready prepared items, mostly single drugs, numbering 962, which may be prescribed in the nominated form only, uncompounded and with certain restrictions The restrictions are some only for pensioners, others for specific diseases, others for children only, some only with special authority The number that can be presented and the number of repeats, if any, are defined. The third section lists some 500 items which may be used in extemporaneous preparations There are set limits to amounts that can be prescribed and repeated in this section also The fourth section is a small formulary called a prescribers' list, which, it is suggested, should be used where possible. The last section is several pages of restricted benefits listed in previous sections and what they are restricted to There is also a separate booklet of proprietary preparations listed numerically and alphabetically Throughout the book the price of the item recoverable by the chemist is listed

Will such a formidable prescribers' book work satisfactorily? Once it has been read and learnt, it should But it will be some months before all practitioners are familiar with it.

The main criticisms of the scheme are

(1) Its complexity

(2) The almost total exclusion of the compounded tablet, despite the increasing popularity of this method of prescribing, with its virtue of stability and often greater economy than multiple tablets and mixtures

(3) The unfairness, in that some patients with certain diseases get everything, while others get very little if anything

(4) The exclusion of such drugs as reserpine, chlorpromazine, and butazolidine (restricted to pensioners), and most anti-histamines

(5) The severe limitations on amounts prescribable, thus often making it as cheap for the patient to obtain his prescription in the ordinary way

From the chemists' point of view it means lower margins generally, and a lot more paper work. The wholesale druggists must come down to the lowest produced figure to be included, unless they have a monopoly of the drug From the practitioners' viewpoint there will be a good deal more work in prescribing till he has become familiar with the scheme. For the patients, prescription costs for allowed drugs will average much the same as before, but those that were not free may now cost more in some cases

Reconstruction

BEDS AT HOSPITAL AND BEDS AT HOME

The Future of General Practice

IN 1948 the hospitals were the axis of medical care in this country. By enabling everybody to have a personal physician, the National Health Service was intended to change their dominating role specialist care was to be recognised as episodic and incidental to the general medical care provided by the general practitioner with his supporting domiciliary services But Mr Gordon Forsyth and Dr Robert Logan, in their important new study made for the Nuffield Provincial Hospitals Trust,[1] conclude that practice has not yet caught up with the fundamental theory of the N.H S Though the cost of hospital care is high and rising, there has been little change either in the hospitals' conception of their place in the scheme of medical care or in the public's attitude to them

This research on the hospital needs of an area has been very usefully amplified into an exploratory study of some of the factors involved in planning the future of the Health Service, and on the role of the practitioner In the concept of comprehensive medical care embodied in the N.H.S , it is the practitioner who should decide whether or not the patient requires hospital care or investigation "in this sense, therefore, the general practitioner is instrumental in determining the case-load to be borne by the hospitals " The introduction to the report quotes a statement that "greater savings could be achieved in a hospital service by improving the quality of general practice than by any other single move "[2]

DEMAND FOR BEDS

Estimates made jointly by the Ministry of Health and the Nuffield Provincial Hospitals Trust in 1941–44 ranged from 450 to 640 acute general hospital beds per 1000 population. But the Trust's surveys in 1950–51 at Norwich and Northampton[3] suggested that in these places the figure might be only about 200 These findings clearly had many implications for those planning hospital services, and further surveys were arranged to take place in industrial areas The one by Mr Forsyth and Dr Logan is the first of these, carried out at Barrow-in-Furness by the University of Manchester in arrangement with the Manchester Regional Hospital Board

Although the bed/population ratio these investigators suggest for Barrow is some 25% higher than the estimates for Norwich and Northampton, it generally supports the belief that the demand for acute hospital care can be satisfied with about 250 beds per 100,000 (at present the actual provision in England and Wales is 310)—in other words about half the beds thought necessary at the start of the N.H S The importance of finding the right number is evident from the fact that an over-provision of 1 bed per 1000 would mean for England and Wales a total of 45,000 additional beds—equivalent to 100 hospitals, whose capital cost at present prices would be about £225 million. The report mentions that between 1937 and 1957 the average stay in acute beds fell from 13 to 7 days in the United States and from 14 to 12 days here.

CLINICALLY UNNECESSARY ADMISSIONS

But how far does the actual present demand equate with clinical need? Discussions in the wards led to the conclusion that at Barrow 40% of the women in medical beds did not—on clinical grounds alone—require inpatient care, and in a further 15% their need of it was doubtful. The corresponding estimates for men were 25% and 21%

When the critical number of beds is adjusted accordingly, Barrow is seen to require 2·3 beds per 1000 population instead of 2·5

"The difference between the critical number and the adjusted figure reflects the impact of conditions external to the hospital service—local housing conditions, availability of domiciliary services, attitudes of general practitioners and so on. In other words, even patients suffering from the same disease may vary in the demands they make on the hospital, and the variation depends on their social circumstances" In Barrow these circumstances, in general medicine and surgery and pædiatrics, "inflate demand to the order of 8 per cent. or 0 2 acute beds per 1000 population"

---

[1] The Demand for Medical Care a study of the case-load in the Barrow and Furness group of hospitals. By GORDON FORSYTH, B.A., and R. F L. LOGAN, M.R.C.P London Oxford University Press. 1960 Pp. 153 7s 6d

[2] Fleming, C. M W.H.O Symposium on the Relations Between the Hospital and its Community Stockholm Nov 3, 1958

[3] Studies in the Functions and Design of Hospitals. London, 1955

But the decision to admit to hospital is often not rational it is usually a matter of custom and tradition, and, rather than the home nursing facilities of Barrow being inadequate, "there was lack of awareness by the general practitioner and others of their full potential"

"In the long run", Mr Forsyth and Dr Logan ask, "would it be a good thing to pare down the hospital inpatient facilities until they accorded with the medical needs as envisaged above?"

"We cannot be at all sure that, however it is organised, general practice will fulfil its theoretical promise within the National Health Service No public service operating on a national scale can hope to recruit the necessary number of altruists, and medical schools are only just beginning to think of teaching medical care outside hospital"

An attempt at Barrow to relate practitioners' use of hospital to the size of their lists, and the location and type of their practices, "cast doubt on the assertions that a reduced hospital case-load could be effected by alone raising the capitation fees and reducing the average size of practice list" The investigators got no support, either, for the view that practitioners who use direct-access diagnostic facilities most send fewest patients to hospital, or that relatively expensive prescribing may be offset by smaller use of hospital beds

GENERAL PRACTICE IN N H S

In their conclusions Mr Forsyth and Dr Logan speak of doubts[4] whether the general practitioner, if he continues in his present role and skills, has any really useful part to play in comprehensive medical care "The argument runs that in the past two decades medical knowledge has expanded so rapidly that it can only be applied effectively by the specialist" But they also quote the Cohen Committee of 1954, which said that "the general practitioner service is an essential not a subordinate service, indeed, in a sense the general practitioner must hold the key position in the Health Service" Systems of medical care are called on to face the problem of all large-scale organisations where there is a high degree of division of labour—someone has to integrate the activities of the specialists

On the operation of the N H S in its first decade they make the following three broad comments

(1) It is all very well in theory to cast the general practitioner as the leader of the new advances in preventive medicine because he has the best chance of undertaking presymptomatic detection *But has he the necessary clinical skill to take up the challenge?* The death-rate from coronary thrombosis in middle-aged men, with anticoagulants available, suggests that he has not. Again, one-fifth of diabetics are undiagnosed and untreated until they present complications In mental illness some 25% of cases in general practice are emotional rather than physical and many go undiagnosed until the manifestations become sufficiently serious to project them into the mental therapy service

(2) It must be confessed also that the removal of the general practitioner from the hospital as a consequence of the regional spreading of consultant services has not helped him to keep in touch with technical advances which have been applied in the hospital and not in general practice the average duration of stay in British hospitals continues to be much longer than in North American hospitals, and one of the reasons, as we have shown in Barrow, is the failure of the general practitioner to integrate the hospital and domiciliary services, for it is at the point of integration that the Health Service has been least *successful*

(3) Even in that sphere becoming peculiar to British medicine, the activities involved in the emotional term "family doctor", certain aspects of the Health Service suggest that after all the general practitioner is not operating as the kingpin of the system For example, the consultants established in the provinces are general consultants and are far less specialised than their teaching hospital colleagues Furthermore the development of almoner and social services attached to the hospitals, and functioning to assist the consultant to relate his treatment to the patient's social and domestic circumstances, can be taken as a reflection of the general practitioner's failure to provide the necessary link between treatment, aftercare, and rehabilitation

The way in which the Health Service has developed in relation to general practice is not, they feel, encouraging "*If there is really to be a renaissance of general practice, instead of merely lip-service to the general practitioner, then efforts must be made to bring the general practitioner back to the hospital*, perhaps with an extension of clinical assistant posts, accompanied by modifications in the method and incentives of remuneration"

Medicine and the Law

Fatal Shock from a Cardiac Monitor

WHILE being prepared for a lung operation in the London Chest Hospital, a patient died on the operating-table when he received a 325-volt shock from a cardiac monitor[1] At the inquest on April 4 it was stated that one electrode had been attached to the patient's thumb, one to his head, and a third diathermy plate-electrode to his right leg This third electrode was connected to the case of the instrument, which was assumed to be at earth potential When the instrument was switched on, the patient moved but, as this usually happens, no particular notice was taken Something was clearly amiss, however, when the surgical registrar received a shock of "some magnitude" from the patient

An electrician who examined the monitor found that the case was not earthed and that there was a broken wire inside Apparently the earthing-connection to the case had been omitted in error, although the instrument had been repaired by the manufacturers at least twice If the plate-electrode had not been fixed to the patient, it is unlikely that he would have received a shock

This seems to be the first reported mishap caused by a cardiac monitor, but it has disquieting implications, particularly since the instrument was a commercial product and not one of the "home-made" instruments that often attract criticism Pre-amplifiers and first-stage amplifiers should be transistorised, and even if the electrocardiogram is to be displayed on a cathode-ray tube, the difficulties of keeping high potentials where they belong are not insuperable "hybrid" circuits are perfectly satisfactory in practice Whenever an earthed, rather than an "earthy", electrode is thought to be necessary, some means should be provided for testing for earth-continuity A suitable circuit is shown in the report of the working party on anæsthetic explosions[2]

In England Now

A Running Commentary by Peripatetic Correspondents

Is it possible that some of today's psychological disturbances are due less to the higher cerebral centres being over-used in reasoning than mis-used in predicting? If so, road-users (which most of us are) should be the first to suffer, because torrents of sensory data about hurtling traffic, flashing lights, and suicidal pedestrians pour ceaselessly into their sensorium, which has urgently to receive, digest, analyse, and then to predict and act upon the result.

This frenzied cerebral stimulation now plays a major part in our lives, and in our deaths, and descends in an avalanche on a brain not designed to cope, at least not often, with objects moving faster than the human body. The original cerebrum as issued to the Neanderthal gent was adequate enough for his "solitary, poor, nasty, brutish, and short" life, whose tempo reached maximum brio with a defiant rock hurled at a passing pterodactyl, or some deft footwork during cultural exchanges with stone-axes and the tenants of the next cave. Even then, such momentary and infrequent frolics involved quantities which were readily calculable and results which were easily predictable by contemporary grey and white matter, even when housed in a brain-pan so shallow that when its owner yawned, the contents slopped over the sides.

Today's integrations require a brain-pan with the dimensions of the Jodrell Bank telescope. Luckily, according to the doctrine of the survival of the fittest, our descendants should get better and better at prediction, and will eventually be able to tell their own fortunes, which should therefore be pretty prosperous ones.

* * *

In the old days if you developed, say, a small rash on one of your legs you showed it to your doctor, and he would say "That's nothing to worry about. Get yourself a small tin of zinc ointment, and it'll clear up in a day or two." So you went to a chemist and bought a 2*d* tin, and at the end of three days, when your rash had gone, you used the rest to lubricate the wheelbarrow or the latch of the garden shed.

Nowadays you sit for forty to eighty minutes in a germ-laden waiting-room packed with people in their Sunday clothes, you and the doctor seem to be the only ones wearing slightly shiny workaday suits. When you eventually get to him you show him your rash.

"Ha!" he says. "A fungus infection. We'll try you with some of this. It is sometimes very effective." You take the prescription to the chemist, and pay him 1*s*, and he tells you "This is the very latest from America, and costs the taxpayer 25*s* a tube."

At the end of a week your rash is still the same, so you go back to the doctor, sit fifty-five minutes in his crowded germ-laden waiting-room, and show it to him again. "Hm!" he says. "We'll try you with this." He scribbles another prescription, muttering as he does so "This is sometimes very effective indeed." You pay another 1*s* to the chemist, who tells you "This is absolutely *the* latest from America, and costs the taxpayer 45*s*."

At the end of three days the rash has broken out on the other leg and the back of your neck. You also have a cold in the head, which you feel sure you caught in the doctor's waiting-room. However, you go and see him again. "Ah!" he says, peering interestedly at the outbreak on the back of your neck. "You must be allergic to the stuff. A lot of people are, you know." He smiles as if he thinks that ought to amuse you, and scribbles another prescription. "We'll try you with this. It's very soothing." You grab the prescription and hurry out before he has time to tell you that it is sometimes very effective. You take it to the chemist, pay him another 1*s*, and ask him nervously what it is. "Zinc ointment," he says. "Quite harmless. I always recommend it for skin complaints."

* * *

A man without a smiling face must not open a shop. If that was true in ancient China, it ought to be true in England today, but as a nation of shopkeepers we seem to be in danger of losing our manners. No wonder I feel rebellious and disgruntled, another Angry Old Man: there is more at stake than my cheque for £5. All I wanted was an assortment of stationery. I usually slip into the firm's Manchester shop, see what they have got, and buy what I need: a pleasant personal arrangement with smiles all round. Manchester is an easy run by car or train, and I often go there for other things. But last month I could not spare the time away and Lakeland was deep in snow, so I wrote out a mail-order and posted it to Manchester.

That was where Free Trade died. Without as much as a by-your-leave I was sold like a slave in a slavemarket across the Pennines to the firm's Newcastle branch. No attempt to check that my order could be met over there: in fact it could not. Part deliveries trickled along Hadrian's Wall and down to Lakeland in the next fortnight, with no advice of when the rest would come, or even if it would come at all. Never the most patient soul, I went berserk with the firm's head office in London. After trying to pull a whole lot of wool over my eyes, their Sales Manager firmly insisted that if I chose to be stupid enough to live in the Lake District I must be allocated to the zone of their Newcastle branch for the convenience of the firm and its commercial travellers.

Now Newcastle is a bonny town and I like it very much, but it is a devilish journey to get there over the Pennines, and there are times when we wonder if some people down in London know just where Westmorland is. But we were never conquered by the Normans, and we are damned if we will be allocated and zoned for our shopping. We claim our right to be freemen in a free market, and we shall throw out these repeated attempts, which are becoming all too common nowadays, to tell us where we are to buy the things we want. I had to counter-attack with a threat to return the whole consignment in protest at such terms of doing business before a half-hearted apology could be wrung out of the firm, with a grudging assurance that I could be tolerated in future as a crank with an unnatural desire to shop where it suits me best.

On following Helen Heardman's advice for the fourth time

After hectic lunchtime with baby, husband, and two sons aged 4 years and 5 years, see latter off in friend's car, put baby in pram to sleep, face mound of washing up, see harried husband back to wards, do urgent mending, then decide to "relax."

Put pregnant cat in kitchen, fetch textbook, empty bladder as directed, turn two dogs off the sofa, settle down in approved position with sigh of content, start breathing exercises. Congratulate self on muscular control. Baby wakes up. Ignore calls. Breathing exercises no. 2, and—yes no. 3. Can no longer ignore baby's calls. Get him up, cuddle, futile attempt at potting, give him book to play with. Telephone rings.

Exercises for pelvic floor contraction. Settle into position. Baby sits on head. Continue with pelvic rocking. Baby sits on stomach. Telephone rings. Baby yells for attention. Give him scissors and fountain-pen to play with!

Exercise for posture correction. Baby spills bottle of milk and breaks glass. Exercise for cleaning floor on hands and knees.

Finally, relaxation. Study requirements: (*a*) Full support of all parts of the body—correct, (*b*) No muscle tension—all right, (*c*) Peace of mind. Give up.

Look at clock. Time to fetch boys from school.

* * *

The *New York Times*, besides all the news that's fit to print, has lately published a large advertisement for insectivorous plants. Perhaps this is because the delinquent scientists have not yet invented an electrical bug-catcher. If so, it must be the only electrical gadget waiting to be invented. Besides such obvious things as electric dish-washers and seats to carry you up the stairs in your house, you can now buy electric shoe-polishers, can-openers, manicure kits, and even pencil-sharpeners. Where will it all end? Perhaps in the box devised by a distinguished engineer of the Bell Telephone Company: this box, it is said, has no function, but if you open it a hand comes out and shuts it.

Letters to the Editor

LEGAL ASPECTS OF HOMOGRAFTING

SIR,—Homografts have already an important place in surgery For example, skin homografts, despite the fact that they are destroyed within a week or two, may be lifesaving in severely burned patients, and on the other side of the Atlantic a whole kidney has been successfully transplanted from an identical twin donor on more than a dozen occasions There are now moreover good grounds for believing that methods will be found of making homotransplants of tissues in general survive permanently in man Progress has also been made in the development of methods of storing tissues and cells in a viable state, though the long-term storage of whole organs is still not possible

Even if the immunological barrier to homograft survival can be removed or surmounted, however, and methods of storing whole kidneys and other organs for days or weeks become available, patients will not reap the full benefit of these discoveries until the legal position regarding homografting has been clarified

The Corneal Grafting Act of 1952 regularises the removal from cadavers, under appropriate conditions, of eyes to provide corneal grafts In New Zealand the Medical Amendment Act of 1954 makes similar provision in respect of all other tissues and organs, but, except as a shining example of enlightened legislation, this is of no help to patients in the United Kingdom In Edinburgh, for example, I have been instructed by my hospital board to refrain from establishing a skin bank on the lines of the one I operated in New Zealand, on the grounds that the law does not permit the removal of skin after death for the purpose of grafting Admittedly one hears from time to time of local arrangements with various authorities whereby the removal of arteries, and on occasions skin, from a cadaver is undertaken provided that the relatives' consent is given, but this is surely not an adequate way of dealing with the problem

If legislation is to be introduced it is to be hoped that special consideration will be given to the fact that, whereas satisfactory corneal grafts may be obtained from eyes removed several hours after death, organs such as the kidney must be removed within a matter of minutes if they are to be of any use

It would seem desirable also that legal provision should be made for the removal of tissues, including the removal of one kidney, from living healthy donors who wish to provide a lifesaving graft for a particular patient At the moment the clearest indication for a voluntary donation of this kind is the desperate need of a kidney by a patient who is lucky enough to have a healthy identical twin, but current work on the use of irradiation and cytotoxic drugs to facilitate homograft survival encourages the view that the range of usefulness of kidney transplants will increase, perhaps very soon

It is clearly desirable that both doctors and laymen should have a proper appreciation of this situation It is surely also desirable that some sort of working party should be set up to study the problem from a medicolegal point of view, and, one would hope, advise the Government on appropriate legislative action

M F A WOODRUFF

FLUORIDATION

SIR,—Dr Dobbs (April 2) rather suggests that because your survey dealt mainly with dental caries in children, it left much to be desired Is not the only reason for most of us being interested in fluoridation that it offers a hope of reducing dental caries to manageable proportions? In this area, before fluoridation, only 2 of every 100 children aged 14 were free from dental disease I have reason to believe that in many parts of the country the position was no better For years, the orthodox advice of a good mixed diet, limitation in the consumption of refined sugar, and regular cleaning of the teeth has completely failed to result in any noticeable reduction in dental caries It is as a result of these facts that many in the Public Health Service feel bound to pay the greatest regard to any substance which can improve this deplorable state of affairs

If Dr Dobbs is prepared to agree, and having had a scientific education, he can scarcely fail to do so, that the effect of the fluoridation of public water-supplies by man is similar to the effect of drinking water which is naturally fluoridated, then surely it is passing strange that in those parts of the country where adjacent villages have water with high and low fluoride levels naturally, the general practitioners practising there have not so far reported any ill effects associated with fluoride This is, of course, a test of clinical judgment, in which Dr Dobbs does not believe I, on the other hand, have seen sufficient of my brethren in general and consulting practice to have considerable confidence in their diagnostic ability

In this area, fluoridation has been in operation for four years and so far no ill effects attributable to it have been reported to me by any local doctor

It appears then that Dr Dobbs does not think much of the clinical judgment of the profession Nor does he place much value in the statistical work of considerable magnitude that has been carried out on the subject He believes that the detection of the alleged risks of fluoridation will prove so difficult as to make it doubtful if they will be recognised at all

Bearing in mind the good effects on the teeth which will result from fluoridation and the great amount of research and experience which have accrued over the years, it would not seem reasonable to withhold these beneficial effects, especially from the children (who cannot write letters on their own behalf) because Dr Dobbs and those who think like him believe, or would have us believe, that certain ill effects which they cannot specify may *possibly* affect *someone* at *some* future date

Health Department,
Kilmarnock

BRUCE R NISBET
Medical Officer of Health

SIR,—As a dental surgeon in general dental practice I would be delighted if some specific such as fluoridation could reduce dental caries Despite the figures produced by many investigators we do not know if fluoridation is absolutely safe to everybody over a period of years Who can really say that an illness occurring in a patient drinking fluoridated water would have still overtaken him had he not been drinking the water?

Does the condition justify the means? Let us face it Teeth are quite unnecessary to survival in our civilisation Their preservation is certainly æsthetically desirable, but that as a reason is simply not good enough to justify adding to water a substance which *may* be toxic to some If dental decay was a killing disease the case for enforced medication of the entire population could be argued In the present state of knowledge it is not a killer and in the present state of knowledge fluoridation is not absolutely known to be safe I think, sir, that it would be a sad day for us all when in the case of a disease of inconvenience we forgot our responsibility to the tiny minority

HUGH V CAPSTICK

Salisbury

FLUORIDATION AND GASTRIC CANCER

SIR,—In a letter in your issue of March 26 Dr Burrowes suggests, by a comparison which he made of deaths in the small towns of Donington and Crowland over a period of ten years, that there may be a relationship between the consumption of naturally fluoridated water and carcinoma of the stomach.

During the period 1952–58 inclusive the number of deaths registered as due to this cause in Donington (population 1917) was 4, average age at death 61 years, in Crowland (population 2833) 12 deaths, average age at death 68 5 years, figures for a 10-year period are not available It will no doubt be agreed that these towns are too small to provide reliable comparative statistics, any deduction therefrom could only be regarded as trustworthy in proportion as the observations were numerous, and on the assumption that the latter were at the same time accurate and comparable

The public water-supplies in Donington (from West Pinchbeck) and Spalding (from Bourne) are derived from bores in the counties of Holland and Kesteven respectively, the average concentration of fluorine being for the former 0 5 p p.m and 0 1 p p.m. at Spalding Dr Burrowes gave the latter value as 0 5 p p.m A bore at Deeping St. Nicholas supplies water with a concentration of 2 9 p p.m F to Crowland this supply came into use about a year ago, the earlier supply from Deeping, according to recent information, contained 3 p p m F As a matter of interest, it is also necessary to take into account the fact that there are indigenous private bores, more common in South Kesteven than in the southern part of the County of Holland, which provide higher concentrations of fluorine This is due to the occurrence of fluorine contours which run in the direction north to south in the extreme south-east of Kesteven and in the south-west of Holland The concentration of fluorine gradually rises from a mere trace in Kesteven to around 4 5 p p.m in Spalding and Crowland in the east.

Local statistics do not appear to support any suggestion that there is a causal relationship between the consumption of naturally fluoridated water and the incidence of carcinoma of the stomach in the natural fluoride areas of South Kesteven Rural District (population 14,394) and Spalding Rural District (population 18,890) The average death-rate from carcinoma of the stomach in the former rural district during the years 1944–58 was 0 29 per 1000 of the population, as compared with an average death-rate of 0 29 per 1000 for the same period for the remainder of the County of Kesteven (population 133,500) which has no naturally fluoridated water in the public water-supplies A similar comparison has been made in the County of Holland, in the Rural District of Spalding, which includes the towns of Donington and Crowland, the average death-rate from carcinoma of the stomach during the years 1952–58 was 0 35 per 1000 of the population, as compared with 0 32 for the remainder of the County of Holland (population 102,600)

During the years 1947–53, the average death-rate for carcinoma of the stomach in England and Wales was 0 33 per 1000 of the population

During the past six years several papers have been published upon various aspects of fluoridation in South Lincolnshire, and these[1–5] may be of interest.

SNAKEBITE

SIR,—Dr Penman (April 2) is to be congratulated on his attempt to preserve our language from further debasement through pseudoscientific jargon While the ugly word, "envenomation", occurs in Webster's New International Dictionary—a most conservative and valuable American work—it is not included in Webster's New Collegiate Dictionary, and, fortunately, cannot therefore be assumed to be of common usage in the United States The equally objectionable French word, *envenimement* (which is to be found even in the Petit Larousse), is, to the best of my knowledge, never used by French writers Let us, by all means, be satisfied with "poisoning" and *empoisonnement*

Bransgore, Hampshire
R. H AHRENFELDT

MATERNAL AGE IN MONGOLISM

SIR,—In presenting an instance where trisomy 22 has not been found in a patient with mongolism, Dr Polani and his colleagues (April 2) lay great emphasis on the youth of the patient's mother at the time of the affected birth In support of their view that mongolism in births to young mothers may be ætiologically distinct from the condition in offspring of older mothers, they quote assertions by Penrose[1,2] that maternal age at birth of mongols is bimodally distributed and that mean maternal age is low in cases where a maternal relative is also affected

But there is nothing remarkable in the finding that a mother of a mongol is young Although the risk of any birth being affected rises sharply with advancing maternal age, the large number of births occurring in the general population at the younger maternal ages results in a proportion of mongols being born to young mothers

In a series[3] of 241 mongols born in Birmingham, 20 (8%) were born to mothers under 25 years of age and 57 (24%) were born to mothers under 30 years of age at the time of the birth Thus, although mongolism is rare among births to young mothers, young women are by no means rare among the mothers of mongols

The hypothesis of Penrose that the distribution by maternal age at birth of mongols may represent the superimposition of two distributions relating to ætiologically distinct groups of cases, depends largely on a demonstration of bitangentiality in the maternal age-distribution of a series of cases assembled from the literature. It is important to consider alternative explanations of Penrose's finding

(1) Since a series assembled from the literature is heterogeneous in respect of the populations of births from which cases are drawn, its maternal age-distribution may reflect differences between these populations in maternal age-distributions for all births Distributions by maternal age for unaffected births exhibit secular and regional variation

(2) The cases in Penrose's series were largely ascertained at some time after their birth and thus are survivors from an unidentifiable population of affected births Since early mortality in mongols is high and related to maternal age at birth, the maternal age-distribution for such a series of survivors may most imperfectly resemble that at birth It is of interest that the series published by Carter and MacCarthy[4] and drawn from consecutive maternity-hospital births exhibits no significant bitangentiality of its maternal age-distribution

(3) Even if the preceding explanations are rejected, an observation that maternal age at birth of mongols is bitangentially distributed is hardly surprising since the distribution is the product of the maternal age-distribution for the general population of births and the maternal age-distribution of the risk that a birth is affected Maternal age at birth for the general population is distributed around a single mode occurring in the 25–29 age quinquennium. The maternal age-distribution of the risk that a birth is affected may be examined by considering maternal age-specific incidence in a series of

TABLE I—INCIDENCE OF MONGOLISM ACCORDING TO MATERNAL AGE AT BIRTH
(Data from Carter and MacCarthy [4])

Maternal age Years Group x	15–19 1	20–24 2	25–29 3	30–34 4	35–49 5	40–44 6	45+ 7
No of cases	0	5	6	25	29	31	4
Incidence per 100,000 births	0	28	29	172	352	1418	2632
dx		−27	+142	+137	+886	+148	

$d_x = n_{x-1} - 2n_x + n_{x+1}$ where n_x is the number of affected in 100,000 births at maternal age quinquennium x

consecutive births Suitable data have been published by Carter and MacCarthy [4] and the distribution of incidences from their series (table I) exhibits *no evidence of bitangentiality* The value d_x ($= n_{x-1} - 2n_x + n_{x+1}$, where n_x is the number of affected in 100,000 births at the maternal age quinquennium x) provides a simple indication of bitangentiality since it has positive values where the distribution curve is convex downwards and negative values where it is convex upwards, so that single negative values surrounded by positive values represent points of upward convexity in an otherwise upwardly concave curve [5]

Dr Polani and his colleagues also quote other evidence published by Penrose [3] that mean maternal age is lower for affected births where there is an affected maternal relative than it is where a paternal relative or no relative is affected Penrose found this lowering most marked where the affected relatives were sibs of the parents of propositi However the data on which these comparisons were based were not numerous, and further data [6] do not support Penrose's finding In the Birmingham series previously referred to, mothers of 217 cases were interviewed and information was recorded on inter alia the existence of affected relatives 6 affected parental sibs were reported Table II shows data on these cases together with those of Penrose, according to whether a maternal or a paternal sib was affected The difference between the mean maternal ages is not significant In any case, where numbers are so small the mean leaves much to be desired as a summarising index, inspection of the distributions themselves is more informative These do not seem essentially different either from each other or from distributions for patients in whom no relatives are affected

Although the motive for examination of the reported patient is stated to be a belief that low maternal age may be a distinguishing characteristic of an ætiologically distinct category of affected, the finding of an unusual karyotype in one case born to a young mother cannot be regarded as endorsing the validity of the belief Fortunately the interest of the report in no way depends on the credentials of the hypothesis that prompted it Together with the report by Dr Fraccaro and his colleagues in the same issue, it provides evidence that mongolism may arise from other anomalies of pair number 22 (21 in Fraccaro's system) than trisomy

"CRISIS IN NURSING"

SIR,—The General Nursing Council is attempting, with the best of intentions, to raise the standard of nursing training, but the course recommended seems calculated to produce what must be in effect sub-standard doctors rather than the well-trained nurse so rightly sought after by Mr Robb (March 26) Surely art is equally if not more important than science in the management of the patient—a consideration that seems to be forgotten by the G N C in its attempts to keep up with the medical Joneses

The laudable attempts of the G N C to streamline training by cutting out teaching for the special diplomas should not mean, however, *a replacement by ever-increasing cramming* with each new fashionable "ism"

With regard to present staffing problems, it might be more logical to accept trainees to a particular H M C group rather than to an individual hospital as at present The major experience would be gained at the main general hospital, but it must surely be to the mutual advantage of all to make use of the powers of secondment implicit in such an arrangement

IMMUNE TOLERANCE IN MOTHER AND FŒTUS

SIR,—In his letter of Feb 27, Dr Michael Galton makes the novel suggestion that the nuclei of syncytiotrophoblast may be haploid His view is based in part on an apparent misinterpretation of Sohval et al [1] Thus he writes

> "Recently, careful search by Sohval and his colleagues has failed to demonstrate the presence of the Barr nuclear chromatin body in the nuclei of these cells (i e, the syncytiotrophoblast) in the placentas of female fœtuses, although it has been identified in every other cell type of such placentas"

They wrote

> "The nuclei least satisfactory for identification of sex chromatin were those of the syncytiotrophoblast In fact, excessive and coarse chromatin granulation made it virtually impossible to ascertain the presence or absence of sex chromatin in these nuclei"

This granularity of the syncytial nuclei is an old annoyance to those interested in the sex particle but, clearly, technical difficulty in demonstrating the particle is not of itself a reason for doubting its existence The practical problem is, of course, to decide which of a number of very eligible particles, on morphological grounds, is in fact the sex chromatin, and in the full-term placenta this can rarely be done with any certainty However, *in young placental tissue*, up to about the 10th week, there can be seen in occasional syncytiotrophoblastic nuclei in female conceptuses a mass of chromatin morphologically identical with the sex particle Suitably non-granular or "transparent" nuclei are scanty even here (and have to be distinguished with care from the nuclei of poorly preserved cytotrophoblast) but they can be found [2] Similarly in hydatidiform moles, scanty non-granular nuclei occur in the syncytiotrophoblast, and in such nuclei an apparent sex particle can also be found, as may be seen in an illustration published three years ago [3]

The difference of the chromatin pattern of the nuclei in the syncytiotrophoblast and in the cytotrophoblast is so marked that it might well indicate a chromosomal difference of some kind, but this cannot be haploidy of every nucleus in the syncytial form That a majority of syncytial nuclei are haploid is, of course, possible, as Dr Galton suggests, but it would not be right to ignore his distortion of Sohval et al , further, as it stands, it is in contradiction with facts as I have found them.[2 3] It is also inaccurate of Dr Galton to say that no account has been taken of the antigenic action of the placenta, this was done in 1959[4]

INFANTILE STRUCTURAL SCOLIOSIS

SIR,—Whilst in no way wishing to be " stirred " into controversy by Mr Denis Browne's letter of March 26, I believe it important to consider a number of his points

It became apparent from studying infants with structural scoliosis of unknown ætiology that there were two groups, resolving and progressive. The former, of which there have been 77, had a structural scoliosis which completely disappeared without treatment. There seems little point therefore in applying splintage. 60–70% of infants with such structural curves belong to this group

The progressive variety, usually (but not invariably) easily distinguished from the resolving, has not, in my experience, responded satisfactorily to any form of treatment, applied early or late. Mr Denis Browne is incorrect in suggesting that we do not treat these children, but having abstracted those undergoing natural resolution, optimism concerning the effects of treatment is not substantiated by the results

Having seen well over 2000 patients in ten years I do not believe that " it is very rare " Mr Denis Browne suggests it is due to malposition in utero, as it may well be. However, in the whole series only 6 were noticed at birth and many not until the second or even third year The progressive curves in these infants are in no way distinguishable from the typical idiopathic curves of the second decade I think it erroneous to blame the intrauterine position for idiopathic curves in infants and ascribe a different cause to those occurring later

LINOLEIC ACID IN THE CHOLESTEROL ESTERS OF THE AORTIC WALL

SIR,—In a paper in your columns in 1958 we reported[5] that the percentage of saturated fatty acids in the cholesterol esters of the aortic wall decreases with increasing severity of atherosclerosis Since then we have extended our analyses of the lipids of the arterial wall and the results will be published soon One of the conclusions we can now draw with certainty is that the linoleic-acid percentage in the cholesterol-ester fatty acids (C E.F.A.) increases considerably with atherosclerosis Our present mean values (determined by gas chromatography) are 24 5% for undiseased aortas and 37% for aortas with atheromas and/or plaques

Sinclair[6] mentioned " a chemical error that has been made in your columns on various occasions by distinguished fat chemists " He pointed out that it has mistakenly been taken for granted that the octadecadienoic acid detected by gas chromatography is identical with linoleic acid, whereas it could equally well be a structural isomer of it. We have now established by ozonolysis and oxidation, followed by identification of the degradation products, that the double bonds of our octadecadienoic acid (isolated from the C.E.F.A. of atheromatous aortas by preparative gas chromatography) are in the same positions as in linoleic acid, infra-red analysis of the same sample (for which we are indebted to the Unilever Research Laboratory, Vlaardingen, Holland) led to the conclusion that more than 98% of these bonds are *cis*-orientated This proves that the octadecadienoic acid isolated from the cholesterol esters of the aortic wall is identical with linoleic acid.

In the C.E.F.A. saturated acids (the mean total percentage of which decreases from 31 to 17%), the largest percentage decrease, relative to the value in undiseased aorta, is found for stearic acid. Since the two most striking changes in the C.E.F.A. are the increase of linoleic acid and the decrease of stearic acid, I would propose the ratio of linoleic acid to stearic acid as an index of the degree of atherosclerosis as reflected by the C.E.F.A. This index increased, in the preparations we have examined, from values between 2 and 7 for undiseased aortas to values between 15 and 35 for aortas with severe atherosclerosis

SERUM-LIPID STUDIES AND NICOTINIC-ACID THERAPY

SIR,—For the past twelve months we have been using large doses of nicotinic acid (3–6 g daily) in the treatment of patients with ischæmic heart-disease Only patients with some clear abnormality of their blood-lipids have been included in our group of 25 We can confirm the favourable reports of Altschul et al[1] and Galbraith et al[2] and of other workers With few exceptions patients have shown a reversal towards the normal lipid pattern

All the disorders were initially detected through a routine blood-lipid study We can confirm that the side-effects of nicotinic acid have been transient and unimportant and are not a serious drawback to treatment. We (like others) have not noted any general development of tolerance to the drug, although twelve months cannot be considered a sufficient length of time to form any definite view on this point.

Included in a full lipid study we do a routine lipid-tolerance test. We have confirmed that many patients with ischæmic heart-disease show an abnormal rise in total blood-lipids after the ingestion of 75 g fat and that this reduced tolerance may be greatly improved following administration of nicotinic acid in large doses This is in line with the work of Pomeranze et al[3] who described an excessive and prolonged rise in total fat acids after a standard fatty meal in patients with arterial disease. They observed some improvement of fat tolerance in these patients when they were kept on a low fat intake.

Our standard lipid-tolerance test is performed as follows

A specimen of blood is taken from the fasting patient 75 g of a synthetic fatty preparation (' Prosparol ' , Duncan, Flockhart) is then administered in a chocolate drink and further specimens of blood are taken at intervals of 2 and 4 hours The patient is kept at rest before and during the test Each specimen is examined for total lipids by Kunkel's method[4], the fasting specimen is also examined for total protein, lipoprotein pattern, and total serum-cholesterol All specimens are examined for optical density, and a clearing test is performed after 4 hours by the intravenous injection of 300 units heparin, the final specimen being taken 15 minutes later

In young healthy adults the lipid rise is rarely more than 100 mg and never more than 150 mg per 100 ml In some patients the rise has been in excess of 150 mg and has been as high as 600 mg per 100 ml This abnormally high rise appears to bear no close relation to the fasting total-lipid or serum-cholesterol levels

An abnormal lipid-tolerance test and/or deficient clearing may be the only unusual findings in this lipid study We have not sufficient experience as yet to correlate lowered fat tolerance or deficient clearing with other abnormalities in blood-lipid behaviour, if indeed such a correlation exists at all We would, however, suggest that a lipid-tolerance test might be useful in studies of patients suffering from coronary or peripheral vascular disease Obviously a number of factors, such as completeness of fat absorption, metabolism or deposition, must be considered in interpreting lipid-tolerance tests The improvement in fat tolerance in some of our patients with coronary disease on nicotinic-acid therapy prompts us to report our impressions at this stage

ELECTROCARDIOGRAPHY AND HYPERKALÆMIA

Sir,—I read with interest the article about the clinical course of uncomplicated acute tubular necrosis by Dr Loughridge and others (Feb 13) in which they state that electrocardiographic evidence of hyperkalæmia is an indication for hæmodialysis

I have seen 10 patients in this hospital with severe uræmia, oliguria, and anuria due to various causes All of them had high blood-urea, blood-nitrogen, and blood-creatinine, and elevated plasma-potassium. Only 3 patients had electrocardiographic evidence of hyperkalæmia, such as tall peaked T waves and arrhythmia 2 patients had equivocal changes The rest did not show any E C G evidence of hyperkalæmia, although the plasma-potassium values were above 7 mEq per litre No T-wave changes, conduction defects, disappearance of P waves, bradycardia, arrhythmia, or ventricular tachycardia were noticed in these patients

I should like to add that the E C G is a poor indication of the degree of hyperkalæmia Sometimes we can see changes with a plasma-potassium of less than 6 5 mEq per litre, and at other times we can see E C G changes only if the potassium is above 7 mEq per litre

Elevation of the plasma-potassium is a better indication for hæmodialysis than E C G evidence of hyperkalæmia

New York City P Narasimhan

THE PSYCHOTHERAPIST AS ARTIST

Sir,—Dr McConaghy (March 19, p 641) mentions the confusion that can be created in the mind of the patient by non-directive psychotherapists But I think that just as impressive a confusion can be created in the mind of the therapist by the patient One feels that no matter what sort of psychiatrist it is, the more confusion he is in, the more he may tend to act aggressively towards the patient with regard to treatment Bearing that in mind, I should like to amplify some of Dr McConaghy's remarks

Psychotherapy is not primarily a scientific discipline, but an artistic activity that involves the creative powers of both the therapist and the patient It is not, by analogy, painting by numbers The latter may be enough or necessary initially—the form of directive psychotherapy Once the patient expresses dissatisfaction by not getting better, he is probably ready to use his own creative feelings, as yet untapped

Here it is that the therapist as an artist becomes involved in creating, with the patient, the evolution of the latter as a mature human being He does this by enabling the patient to become aware of his feelings and of his ability to create with them a more satisfactory relationship for himself

Susanne Langer states that what is artistically good is whatever articulates and presents feeling to our understanding This is precisely what psychotherapy is about

Although our material is human, we also feel involved in its creation. Not only is it in our image, but the patient also has the ability to use the creativity that he finds in himself Thus proclaims his unique being—to be judged not as a cure but b his value as a human being (that is, not in scientific term only, but also in artistic ones)

London W 5 F J Lichtigfeld

ROLE OF POTASSIUM IN MALIGNANT DISEASI

Sir,—It has long been known that potassium plays som part in the metabolism and growth of tumours An averag estimate of the potassium content of benign tumours ha been given as 1 4% of tumour weight, and that of malignant tumours as 2 3% [1] In 1946 Brunschwig [2] recorded series of gastric carcinomas that were analysed fo potassium content, and compared the results wit similar analyses of gastric mucosa from patients with n carcinoma The average potassium content for the forme was 292 4 mg per 100 g of tumour, and for the latter 217 5 mg per 100 ml Similar studies were carried out for carcinomas of the colon and adjacent mucosa The increase in potassium content of the carcinomas relative to the mucosa was rather striking,[3] the average for the carcinoma being 317 mg per 100 ml, and for the uninvolved mucosa 192 mg per 100 ml More recently attention has been drawn to potassium-secreting tumours by Roy and Ellis [4] There therefore seems to be little doubt that with few exceptions the potassium content of malignant neoplasms is higher than a similar weight of normal tissue

The amount of potassium in the adult body is of the order of 150–200 g Of this amount, 3 g is in the extracellular fluid, so that the remaining great bulk of body-potassium is intracellular and intranuclear—i e, over 95% There are three naturally occurring isotopes of potassium, ^{39}K, ^{40}K, ^{41}K, with an abundance of 93 08%, 0 0119%, and 6 91% respectively ^{39}K and ^{41}K are stable, but ^{40}K is a radioactive isotope, present therefore to the extent of 12 parts in 100,000 of the ordinary mineral potassium, and possessing a half-life of 1 3 × 10^9 years In spite of this very long half-life, the emitted rays possess considerable energy, 1 4 meV beta radiation, and a very hard gamma radiation 1 5 meV, to the extent of about one-tenth of the total

^{40}K is the principal natural source of radioactivity in the human body, and life as such has evolved in the presence of this small radiation, though it has been established that this radiation is not essential to life [6] Could, however, this radiation ever be harmful? Certainly not under the average concentration of ^{40}K within the cell The dose is extremely minute and the span of human life far too short for any observable effect of this very low-intensity radiation The question, however, would be open for argument if it could be proved that this average concentration in the cell was, in fact, subject to fluctuation That this is so is shown by an analysis of the body-potassium in 10 subjects The total potassium content of the body, calculated as a percentage of body-weight, varied from 0 17 to 0 24 [7] Though the kidneys are very efficient in sweeping out excess potassium, there is a time-lag in this excretion, and therefore a continuous high intake of potassium necessarily implies a continuous high intracellular content of this cation

It may be presumed that any excess intracellular content is of no special significance bearing in mind the extremely minute dosage of this low-intensity radiation, what, however, if it could be further proved that the ratio of the radioactive isotope to the stable isotope was variable? This fact could then indeed be very pertinent. Investigations have disclosed the somewhat surprising fact that the abundance ratio of the isotopes of potassium is not a constant figure for all organic

tissue. In other words, fractionation of isotopes is a proven fact in Nature.[8] Lasnitzki and Brewer carried out an analysis of potassium in human cancer, and found that the isotopic ratio ^{39}K/^{41}K of potassium in tumours showed, if compared with that of mineral potassium, a slight but definite increase, thus indicating a corresponding decrease in the percentage of the heavy isotope ^{41}K. In an analysis of the potassium content in eleven cases of human cancer, the average percentage of ^{41}K was 6·5 (normal 6·9), the average isotopic ratio ^{39}K/^{41}K being 14·3 (normal 13·5). Since a deviation of this kind could not be observed with potassium in any of the normal tissues, it appeared that the isotopic constitution of potassium in normal tissues and tumours was appreciably different.[9] In addition, it has been found that the potassium content of muscle from tumour-bearing animals, compared with the potassium in muscle from normal animals, showed a deviation similar to that observed with potassium in tumours,[10] a finding of possible significance.

In other words, fractionation of the isotopes of potassium by the renal tubules or cell membranes is a physiological possibility, and in cases of cancer it seems that there is a selective affinity for the lighter isotopes, including ^{40}K. The body is therefore carrying out a process akin to the electromagnetic separation of isotopes as carried out in the laboratory, and there is no reason to suppose that ^{40}K as well as ^{39}K would not be fractionated in the same way. There are therefore two separate factors for consideration, the first, that the intracellular content of potassium can be permanently in excess of body requirements, and that this would carry with it an increase in the minute intracellular radioactive content, the second, that this minute intracellular radioactive content may be further stepped up by a physiological fractionation of ^{40}K.

One might expect that tissues containing a large amount of potassium would be more liable to undergo malignant change. This is not necessarily true, since cancer-prone cells are those that undergo frequent mitosis, as for example the cells of the respiratory, alimentary, and endocrine systems. Mitosis is rare in muscle tissue, and so are neoplasms. It is true, however, that individuals on a high-potassium diet appear to be more liable to develop cancer. This association is firmly supported by circumstantial evidence.

The incidence of tumours in animals is greater when they are fed on a liberal diet compared with those fed on an adequate but low-calorie diet, and it is also clear that there is a relationship between national income and diet, and national income and cancer. The higher the annual budget per head of population, the greater the incidence of diagnosed cancer, and this seems to be associated with the fact that the higher the income of the country the greater the amount of food consumed.[11] Further, the consumption of protein and fat increases with the income of the country, and it is these foods that are high in potassium content.

The biological effects of high-intensity radiation are well known, but little or nothing has yet been learnt about the effects of low-intensity radiation on the human body. This is partly accounted for by the fact that most experimental animals are unsuitable owing to their short span of life, in other words, these animals would die in the natural course of events before any effects of this low-intensity radiation became apparent. This extremely minute radiation is undoubtedly increased by the storage of large amounts of potassium—e.g., many times the amount required to carry out all normal physiological functions. How much more could this minute radiation be increased as the result of the selective affinity of the renal tubules or cell membranes for the lighter isotopes ^{39}K and the radioactive ^{40}K? And how significant could this be when it is realised that this radiation is both intracellular and intranuclear—in other words, placed at the fountain head of mitosis.

It is not suggested that potassium is a causative factor in all cancers, indeed, the number of known carcinogens increases daily, each one more powerful than its predecessor. What I put forward for expert thought, however, is a hypothesis that potassium could be an initiating factor in the onset of an ordinary non-industrial type of cancer.

A NEW FILM

SIR,—May I make a brief comment on your very fair review of April 2 (p. 777) of the film *They Breathe Again?*

The film is intended primarily for nurses, as well as for medical men who may never work in a respiratory unit, but may find useful a clear statement of the whys and wherefors in dealing with the types of poliomyelitis most dangerous to life. For this reason the question of biochemical control and the regulation of pulmonary ventilation were deliberately omitted, and these two subjects would seem to merit the production of a separate film.

The Drager meter was used because of the larger size and clarity of the dial.

I should add that the film can be borrowed from the hospital free of charge.

PLACENTA PRÆVIA

SIR,—Certain points that arise from Professor Macafee's reply (April 2) need further discussion.

(1) It is not merely the "occasional case" of antepartum hæmorrhage in which there is doubt about the cause of bleeding. In practice the problem is arising continually. Major placenta prævia usually causes no diagnostic problem but rather the lesser ones in which bleeding can still be dangerous.

Displacement of the presenting part as a sign of placenta prævia is used alike in clinical and radiological examination, yet the difficulty of relying on clinical examination alone in many cases is shown by the fact that even when there are both antepartum hæmorrhage *and* a high head, there will be found just as many cases without as with placenta prævia. For instance, in our series only 13 out of 50 cases of placenta prævia showed significant displacement of the presenting part along with bleeding, yet out of 84 other patients who bled and subsequently were proved not to have placenta prævia no less than 25 were found to have a high head.

That is the diagnostic problem which we feel can best be solved in selected cases by placentography, avoiding dangerous complacency on the one hand and overanxious conservatism on the other.

(2) Professor Macafee has stressed the placenta prævia that has already begun to bleed. Surely it is even better to teach our students and still more so our future consultants (especially in these islands where conditions are favourable) to watch for the signs of placenta prævia *before* bleeding begins. Selective placentography can play an important part here too.

If there is doubt about this Professor Macafee himself has surely dispelled it in his account of discovering *by accident* a number of cases (six, I think) of major placenta prævia at cæsarean section for other reasons.

This too stresses the importance of noting the difference between a high or elevated head not approaching the brim, and merely the unengaged one that does. The advantages that soft-tissue placentography can offer to the discerning outpatient clinician in such cases seem too obvious to mention

(3) The X-ray risk with ordinary care has been greatly exaggerated according to the most recent reports by enlightened authorities, so too have the number of films needed for placentography. The four mentioned by Professor Macafee have seldom if ever been used by us—one is the more usual.

The London Hospital,
London, E 1

Robert Percival
Stanley Murray

EFFECT OF HEPARIN AND Ro1-8307 ON KALURESIS

Sir,—In their letter of March 5, Dr Muldowney and Dr Banks drew attention to a kaluretic effect after intravascular injections of heparin in short-term experiments in normal and adrenalectomised dogs.

We are able to give comparable results in humans as some of our patients received a diet for the study of diurnal excretory rhythm, described in our article of Feb. 6 as the diet *a* (eight identical meals each day, urine collections every three hours). The patients received heparin (75 mg.) or the heparinoid Ro1-8307 (100 mg.) by intravenous route every six hours.

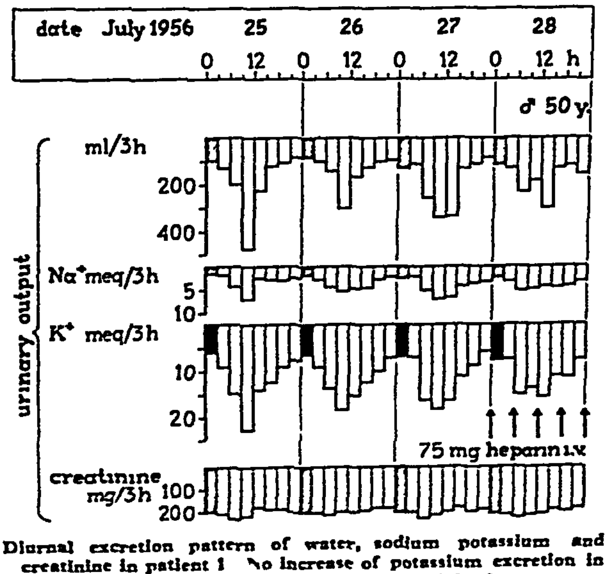
The accompanying figure shows the diurnal excretion pattern of water, sodium, potassium, and creatinine in a patient with coronary insufficiency without signs of heart-failure. The first heparin injection was given on July 28 at 0.00 A.M. When we compare the excretion of potassium in the period 0.00 up till 3.00 A.M. (black columns) on July 25, 26, and 27 with July 28, no increased urinary excretion of this ion was recorded during the three hours after the first heparin dose.

The effect of heparin or Ro1-8307 on urinary sodium and potassium excretion during the three hours after the first intravenous dose in 14 patients is shown in the table. All patients were on the same type of rigorously standardised diet. Mean potassium outputs during identical three-hour period(s) of preceding day(s) are given as control values.

Patient 12 had undergone total adrenalectomy for metastatic cancer of the breast and received as substitution therapy 12·5 mg. of cortisone acetate, 0·25 mg. of 9-α-fluorohydrocortisone, and 2·5 g. of succus liquiritiæ every six hours.

Patient 14 had suffered from Addison's disease of unknown origin and received every six hours 0·1 mg. 9-α-fluorohydrocortisone and 2 mg. of prednisone.

It is apparent that we never found a significant change in the excretion of potassium during the first hours after heparin or heparinoid administration. We cannot explain the interesting but deviating results found in dogs by Muldowney and Banks. They do not mention the weight of their experimental animals, but we have good reason to believe that the dose of heparin they used in dogs was larger than the dose we gave to our patients, when compared on a weight basis. We agree with Muldowney and Banks that the rapid kaluretic effect they found after heparin injections in dogs cannot be ascribed to an alteration in aldosterone secretion and thus must be clearly distinguished from the aldosterone-dependent natriuretic effect we have studied in humans.



Diurnal excretion pattern of water, sodium potassium and creatinine in patient 1. No increase of potassium excretion in the three-hour period after the first heparin injection.

COMPARISON OF URINARY EXCRETION OF WATER, SODIUM, POTASSIUM, AND CREATININE IN THE THREE-HOUR PERIOD AFTER THE FIRST INTRAVENOUS INJECTION OF HEPARIN OR Ro1-8307, WITH EXCRETION IN IDENTICAL PERIOD(S) OF THE PRECEDING DAY(S)

HÆMOGLOBIN STANDARD

Sir,—In 1955 the Protein Commission of the International Union of Pure and Applied Chemistry considered the problem of standardising the value of the iron content of hæmoglobin in blood, and following their recommendation 100% Haldane became equivalent to an iron content of 14·6 g. per 100 ml.

As a peripatetic pathologist I have had the opportunity to observe that in some laboratories this recommendation has borne no fruit and that the 100% standard remains at 14·8 g. per 100 ml. This may also apply to many laboratories which I have not visited. Upon asking the reason for this non-conformity I have been told that the correction of so small a difference entails the expenditure of a relatively large amount of trouble, and as a peripatetic pathologist does not choose to appear offensively critical of his colleagues, I have accepted so common-sense an answer, for it is true that *the difference is a very small one, and clinically insignificant*. The real danger, *however, is not to the patient but to the pathologist*, for in this competitive age the pathologist cannot afford knowingly to expose himself either to the charge of individualism, or of non-conformity, or even (if it must be said) of being behind the times.

N.H.S DISCIPLINARY TRIBUNALS

SIR,—It is time that a protest was made against the iniquitous system of trying complaints against general practitioners The harassed general practitioner is at the mercy of any Tom, Dick, or Harry whose dislike he may be unfortunate enough to incur The decision to proceed with a complaint is in the hands of a lay chairman, who is, therefore, deciding on matters of medical diagnosis and treatment. Even when the whole Service Committee is consulted, there is still a majority of lay persons, and the chairman holds the casting vote This is as ludicrous a situation as would pertain if a doctor were placed in command of a tribunal hearing complaints against lawyers

There is, or should be, one system of justice for everybody in this country The public has full access to the legal machinery, and there is the added safeguard of the General Medical Council If a doctor is accused of failing in his medical care of his patients, then he should be entitled to the same legal privileges enjoyed by the remainder of the population Instead, he is subjected to a humiliating and time-wasting procedure in which the scales are weighted heavily against him from the start.

It is my intention, if ever called before one of these tribunals, to refuse to have any communication with the committee whatsoever It is perfectly legitimate to do this under the N.H S Act In the event of the committee finding against me, then I shall, on appeal to the Minister, provide full information on my side of the case In the majority of instances these complaints are frivolous If this procedure was adopted by everyone, the Minister would be in the position of having to reverse many of the decisions of the committee In this way the proceedings of the committee would fall into disrepute, and something might be done about this unjust and unBritish procedure

Twickenham DAVID WHEATLEY

URINARY EXCRETION OF 5-HYDROXYINDOLEACETIC ACID AFTER REMOVAL OF THE LARGE INTESTINE IN MAN

SIR,—One of us described[1] the effects of removal of the large intestine on the biosynthesis and metabolism of 5-hydroxytryptamine (5-H T) in the organism of the rat. Particular attention was paid to the quantitative estimation of the urinary 5-H.I.A.A. as a reliable index of turnover-rate of extracerebral 5-H.T.

A striking reduction (up to 40 or 50%) in the daily urinary excretion of 5-H I.A.A. was found after removal of the rat's large intestine.

The presence and distribution of the enterochromaffin-cell system and consequently the quantity of 5-H.T in different parts of the gastrointestinal tract have been extensively studied in many species, although they are practically unknown in man. From the data given by Erspamer[2] it seems, however, that the large intestine contains, even in man, a remarkable amount of 5-H.T We therefore investigated the rate of 5-H.T metabolism in seven patients suffering from ulcerative colitis, and operated on for removal of the large intestine. Information on their 5-H.T metabolism was obtained by estimation of urinary excretion of 5-H.I.A.A. Urine was collected over a 24-hour period and its 5-H.I.A.A. content was estimated by the colorimetric method of MacFarlane et al.[3] In most of the cases urine was collected approximately 6 months after the operation. Healthy subjects, under the same conditions as regards age, diet, and season, acted as controls Results were as follows

5-H.I.A.A content of urine

Controls (mg per 24 hr)	*Operated subjects* (mg per 24 hr)
4 24	2 10
4 80	1·65
3 36	0 84
2 70	1 20
1 80	1 15
1 20	1 33
5 87	1 82
1·60	
1 80	
* 3·04±1 24	* 1·44±0·39

P <0·05

* Values expressed as means, plus or minus fiducial limits t=0·05

These results agree with those obtained by Haverback,[4] who found the daily excretion of 5-H I.A.A. varying between 0 36 and 1 06 mg in a patient whose large and small intestine had been resected. They suggest that in man too gastrointestinal mucosa is the main site of production of 5-H.T appearing in the blood, and hence of urinary 5-H.I.A.A.

AGRANULOCYTOSIS AND THROMBOCYTOPENIA ASSOCIATED WITH ARTHRIPAX

SIR,—In the case described below, pancytopenia developed after the patient had been taking a preparation containing salicylamide, mephenesin, and aluminium glycinate for 6 weeks

A man of 49 was first seen on April 7, 1959 He was obviously very ill, his temperature was 104°, and he was complaining of a sore throat, which was found to be very inflamed, with three or four small pustules on each side. He had been taking 2 'Arthripax' tablets three times a day for the previous 6 weeks Each tablet contains salicylamide (gr 5), mephenesin (gr 1), and aluminium glycinate (gr 1$^1/_2$) The tablets had been given to him by a "man who did massage" (not a registered physiotherapist) His first symptom, a sore throat, developed on the afternoon of April 5

Blood examination, carried out within 48 hours of first symptoms, and within 2 hours of first being seen, showed hæmoglobin 11 8 g per 100 ml , the white cell count (W.B.C.) was 20 (Dacie's method[5] normal 4000–10,000) As there were so few white blood-cells, no differential count was done. The blood-urea was 40 mg per 100 ml A diagnosis of agranulocytosis was made, and a pint of stored blood was given. A swab taken from the throat yielded a growth of pyogenic streptococci, sensitive to penicillin and streptomycin, and he was given these drugs

April 9 no white cells (Dacie s method), none in 100 oil-immersion fields (normally 2–4 are found per oil-immersion field)

April 10 a pint of fresh blood was transfused vein-to-vein Towards the end of the transfusion, the patient had a severe rigor, and was given an injection of 25 mg of promezathine

April 11 the patient deteriorated, he was tired, weak, and unable to sleep, his throat was covered with a white purulent exudate, the lymph-nodes were enlarged and tender, and he was jaundiced W.B C. 28, no polymorphs in the stained film Platelets reduced to 23,000 per c.mm (normal 250,000–400,000) Serum-bilirubin 5 8 mg per 100 ml (normal 0·5–1·0)

April 12 he was much worse and seemed to be dying He was given intravenous tetracycline and prednisone. Hæmoglobin 9·7 g per 100 ml , W.B C. 750 per c.mm., in 50 oil-immersion fields there were 7 lymphocytes and 1 monocyte, no polymorphs

April 13 W.B C. 1500, no polymorphs He appeared a little better

April 14 W.B C. 1300, only 1 polymorph in 50 oil-immersion fields. Clinically, there was a slight improvement.

April 15 W.B C. 2100 (100 polymorphs, with an occasional myelocyte)

April 17 the patient was improving, W.B C. 5900 (nearly 4000 polymorphs)

---

2. Erspamer, V *Rendiconti scien. Farmitalia* 1954 1, 1
3 MacFarlane, P S , Dalgliesh, C E. Dutton, R W , Lennox, B , Nyhus, L. M., Smith, A. N *Scot med J* 1956, 1, 148

4 Haverback, B J , Davidson, J D *Gastroenterology* 1958, 35, 560
5 Dacie, J V Practical Hæmatology London 1956

April 18 jaundice fading, serum-bilirubin 1 4 mg, alkaline-phosphatase 7 King-Armstrong units (within normal limits), thymol turbidity 5 units (normal 1–4), zinc sulphate 20 units (normal 1–12), and ammonium sulphate 6 5 units (normal 1–6)

April 19 W B C 9600 (about 7000 polymorphs)

He made a complete recovery and was discharged on May 5 and has remained fit

In addition to blood-transfusion the patient was treated with penicillin, streptomycin, and intravenous tetracycline, nystatin, and prednisone

It is assumed that arthripax was the cause of the illness Whitby and Britton[6] list over 40 preparations that have been thought to cause agranulocytosis, and Wintrobe[7] mentions others, but arthripax is not included Platt[8] described a case of thrombocytopenia following arthripax, and Hillier[9] recorded another In both these cases, although the platelets were worst hit, the other blood elements suffered

Jaundice can occur in agranulocytosis[7], *in our patient* we do not think the jaundice was due to mismatched blood or to red-cell destruction, but probably to liver dysfunction—a view supported by the altered flocculation tests

It is hard to explain the absence of hæmorrhages, despite the dangerous level of the platelets

The patient seemed to respond better to intravenous tetracycline than he did to penicillin and streptomycin

The value of blood-transfusion in these cases is not proven Whitby and Britton[6] feel transfusion is of doubtful value, Wintrobe[7] regards the results as inconclusive, and Cecil[10] does not mention transfusion in the treatment of this condition We know of no evidence that fresh blood contains a factor that can stimulate the marrow, and it seems unlikely that the number of transfused polymorphs would be of any value

Agranulocytosis caused by drugs (except amidopyrene) usually appears during or after the 4th week of continuous treatment, but the onset may be earlier in sensitised patients It is probably useless to do routine weekly white counts when the patient is on a potentially dangerous drug, as the onset of agranulocytosis is sudden—within a matter of a few hours[10] All that can be done is to warn the patient who is taking a potentially dangerous drug that if fever or a sore throat develops he should stop the drug and seek immediate advice

We wish to thank Dr J G Green for his courtesy in letting us use the notes of a patient under his care

Worthing

P MURPHY

VITAMIN E FOR ATHLETES

SIR,—Three years ago I learned from some of our athletes returning from the Melbourne Olympic Games that vitamin E was being given extensively to athletes in Australia, and the phenomenal success of their athletes and swimmers encouraged me to carry out a trial here We had then no detailed information, so our first trial was very much a pioneer effort, for which we chose members of the athletic club over a period of some two months Although the results were statistically of little value we were sufficiently impressed by some of the clinical results to attempt a further trial last year

Our impression was that its value, if any, lay in increased stamina and delayed fatigue, so this year members of our senior eight rowing team volunteered for the trial, which was carried out over a period of three months Again the results were very encouraging, especially from the clinical point of view, the crew having the most successful year in the annals of the club

This year we are attempting a much more comprehensive trial using as our volunteers six trained athletes, six untrained but starting training, and six untrained who will remain so, having no interest whatever in games or exercise of any kind. The trial has been planned statistically using several physiological tests at regular intervals under exactly similar conditions each time and including forced expiratory volume and a modified Cotton ergometer The trial will be carried out over a period of three months and is hoped will provide a true index of the value of vitamin E in athletics

WILSON JOHNSTON

A PORTABLE FREE-FIELD AUDIOMETER

SIR,—The audiometer described by Mr Denes and Mr Reed[1] would no doubt be very useful to obtain some approximate indication of the hearing capabilities of a subject who could not be tested using a normal audiometer

Pure-tone audiometry is normally carried out by earphone listening and if the equipment complies with all the requirements of British Standard 2980, should enable readings from the same subject to be repeated to an accuracy of 5 dB The use of earphones enables each ear to be assessed separately and in particular it makes the measurement independent of the sound-reflecting quality of the room in which the test is carried out

When a loudspeaker reproduces a fixed frequency of pure tone in an ordinary room, multiple reflections of sound occur from the walls and ceiling At one point in the room the reflected sounds can reinforce each other to give a point of high sound intensity, while at another point in the room, only a short distance away the reflected sounds tend to cancel out to give a point of minimum sound intensity This can easily be observed using an ordinary radio or television receiver to reproduce the 1000 c/s "tuning note" which the B B C broadcast prior to the commencement of the programme If the observer blocks one ear, the sound heard by the other ear will be found to vary considerably in intensity when the head is moved just a few inches in one direction or the other It may even be found that the sound heard in a corner of the room opposite the loudspeaker is louder than when the ear is only 3 or 4 feet away from the loudspeaker This simple experiment will illustrate the powerful effect of room reflections on the sound reaching the eardrum

To obtain acoustical conditions free of these disturbing reflections an acoustically treated "anechoic" room is necessary and this can be very costly The *Wireless World* article makes reference to the subjective calibration of the invention in such an "anechoic" room and this calibration does not correspond to the conditions under which it will normally be used

Wembley,
Middlesex

J P ASHTON
Director and Chief Engineer, Amplivox Ltd

*** Mr Ashton's letter was shown to Mr Denes and Mr Reed and their reply follows —ED L

SIR,—Concerning Mr Ashton's comments on the use of the free-field portable audiometer, we have no doubt that his observations with reference to acoustics and room conditions are quite accurate, yet in relation to the use of this instrument as described in *The Lancet*, they seem irrelevant

Mr Ashton writes, as if this is a minor point, "the audiometer would no doubt be very useful to obtain some approximate indication of the hearing capabilities of a subject who could *not be tested using normal audiometry*" In fact, this is almost the only reason for this instrument One other use is to prepare a child for normal pure-tone audiometry

In our article, apart from the description of the instrument's physical properties, all else was devoted to its use in circumstances in which normal pure-tone audiometry could not be carried out

The procedure will show whether at some time or other the child will respond in some way or other to various frequencies

[1] Denes P, Reed, M *Lancet*, 1959 ii, 930 (a technical description of the equipment appeared in *Wireless World*, Dec, 1959)

If the child does respond, then this is a positive indication of some hearing at that frequency In the fullness of time a qualitative picture can be built up which, together with other evidence, will enable the clinician to establish a reasonable diagnosis

There are many children who, in these days of emphasis on early and correct diagnosis, present a behaviour pattern which makes it difficult to establish whether the child is mentally retarded, psychotic, or deaf Often, of course, a slight degree of many of these conditions is present.

Awareness of a rattle may give insufficient information Awareness of pure tones may give much more information. The exact level is not always so important in such circumstances, and often cannot be obtained from a particular child for too long a lapse of time. However a qualitative picture as may be given by the use of this instrument will often enable the clinician more readily to make a decision on further training

MICHAEL REED

JUDO

SIR,—We were interested to see reference [1] to judo as a possible alternative to boxing in schools As holders of both medical qualifications and judo black belts, we write to support the suggestion that the health and educational value of judo deserves serious attention

The immediate practical value of judo as a means of self-defence is, we feel, only a minor consideration Real proficiency requires intensive work along lines different from those of judo as a sport, although the latter can form an ideal basic training for the subsequent study of self-defence

If fact the most direct application of judo skill to ordinary life comes from the training and constant habituation in falling safely from all angles For example, motor-cycling judo players sometimes have striking demonstrations of the value of a spontaneous judo fall. The management of the body in falling is the beginning of judo training, and its achievement may have more than superficial effects, it appears to play a part in the increasing self-confidence often shown by nervous young men who have taken up judo

But no sport can be assessed on its specific applications much more important is the influence on personal development as a whole and its enjoyment value. These things are not entirely to be dissociated, for, while development depends on effort, effort to be constructive must also be enjoyed.

Here judo does seem to be of wider value than boxing by virtue of its greater scope and adaptability Judo attack and defence comprise many different types of movement, and the style of each individual, and the actions which he principally uses in attack, tend to select themselves according to his physique and natural inclinations Each can make the most of his own size, build, and proportions (there is no need to match opponents for weight and size) Progress in judo is marked by a system of grading according to skill, and it is this that provides the basis for matching opponents The big man and the small man of equivalent skill fight, as it were, with different weapons but can be equally effective. Contests between them will thus be decided mainly by such factors as confidence, personality, and style. Often aggressiveness of movement rather than size or power determines the result.

A judo contest can be a very intense process, but the demands of judo training arise in a gradually progressive manner which can allow even a very weak novice to adapt himself to them smoothly without the deterrent effect of trauma, mental or physical, at a stage before he is ripe to withstand it. He can get something very positive out of the early stages even if he never acquires much contest proficiency, although the latter is one of the aims upon which his training is oriented and which gives it meaning and direction.

The basic elements common to all varieties of judo style and action are principles of posture and movement which could be discussed at great length, but in a well-guided training they are of course assimilated in practice rather than presented intellectually In essence the postural demands of judo proficiency are the release of the natural flow and coordination of movement from the influences which so commonly distort them. Any sport at its best should have a similar effect, but judo seems to differ from others in that correct natural movement is so critically and specifically essential to effectiveness

Furthermore, in judo this posture needs to be a continuous background to all activity, whereas, for example, a golfer (in whose actual stroke, posture is equally important) experiences this in a much more specialised connection and is under no demand to maintain it between one stroke and the next. Hence the lessons learnt on the judo mat seem to permeate general activity more potently than those learnt in other sports

We think that this is one of the major benefits of judo in physical development. This is not to say that judo practice is not also accompanied by improvement in emotional as well as physical poise and often too by an impressive gain in weight and generalised muscular development. Of course, judo practice needs to be effectively supervised and wisely guided by a sound teacher and these are still scarce (but getting less so) Thus the major obstacles to the development of judo in schools are this difficulty in finding good instructors, and occasional prejudice against judo, based on misconceptions as to its true nature.

Parliament

Children in Prison

ON April 6 under the ten-minute rule Mr ALAN BROWN asked for leave to bring in a Bill to restrict the committal to prison of children under 16 years of age and to provide for the transfer to remand homes or remand centres of children who have been so committed. Everyone had been shocked when it came to light three weeks ago that a 14-year-old girl, originally in trouble for playing truant from school, had been sent to Holloway on remand and placed in a ward with women accused of murder On March 22 Mr Brown had visited Wormwood Scrubs, and found nine boys below school-leaving age imprisoned there. There were two prison blocks within the outer wall of this prison One block was the " boys' " prison and the other was the " men's " prison. The boys' prison contained persons in the age-range 14–21, and there was a real danger of the possible criminal indoctrination of the schoolboys by the older youths of the " young adult " class The children were locked individually in the ordinary type of bare comfortless prison cell measuring about 7 ft. by 10 ft. There were no educational facilities

The concept that a child might not be imprisoned for any reason whatsoever before he or she reached the normal end of compulsory school attendance was already the accepted practice in most countries The argument which had received most publicity against it in this country was that if we released the children from prison there was nowhere else to send them But if shortage of remand homes was to be pleaded why, he asked, had so many been closed down in recent years? Between 1951 and 1955 18 remand homes owned by local authorities were closed down, with a consequential loss of 495 places, and the country was left with 36 remand homes for boys, 14 remand homes for girls, and 1 remand home for boys and girls all provided by local authorities, and 10 remand homes owned by voluntary organisations Since then there had been a net loss of 8 further remand homes So far as he could ascertain 120 to 150 children were at the moment lying in prison

QUESTION TIME

Antibiotics in Animal Feeding-stuffs

Lord DOUGLAS OF BARLOCH asked H M Government what was the extent of the use of antibiotics in the feeding of animals intended for human consumption —Earl WALDEGRAVE, the joint parliamentary secretary of the Ministry of Agriculture, Fisheries, and Food, replied The sale or supply of compound feeding-stuffs and supplements containing antibiotics, other than on veterinary prescription, is confined by statute to pig and poultry foods containing penicillin, aureomycin, or oxytetracycline in certain prescribed and limited proportions Under regulations, based on advice from the Agricultural Research Council in consultation with the Medical Research Council, the inclusion of these substances in manufactured feeding-stuffs is restricted to food for young pigs and poultry intended for early slaughter Within the permitted categories of pigs and poultry the feeding of antibiotics, which may lead to improved rates of growth and better food conversion, is thought to be fairly widespread, but I regret that no precise information is available This subject, however, is complex, and a joint committee of the Agricultural Research Council and the Medical Research Council is shortly to review the whole problem Lord DOUGLAS OF BARLOCH May I ask whether there is any means by which a person purchasing either poultry or pig products can know whether they have been treated in this way or not? Earl WALDEGRAVE No, I do not think there is any means

Hospital Building

Hospital capital expenditure for 1938–39 was of the order of £32 million, or about 0 17% of the national income at the time The most nearly comparable figure for 1954–58 is of the order of £57 million, which would correspond to about £16 million at the prices ruling in 1935–39 It is about 0 09% of the present national income

Merit Awards

For 1959, 216 awards were given to consultants, divided by specialties as follows

Obituary

JAMES MacCONNELL KILPATRICK

K B E , C B , M B , LL D Belf , D P H

Air Marshal Sir James Kilpatrick, director-general of the medical services of the Royal Air Force from 1951 to 1957 and subsequently dean of the London School of Hygiene and Tropical Medicine, died in London on April 4 at the age of 58

Elliot & Fry

An Ulsterman born and bred, he was educated in Belfast, graduating M B from Queen's University in 1924 The following year he joined the Royal Air Force Even as a junior officer he was outstanding and it was obvious that he would be a candidate for the highest rank in the medical branch He had a leaning towards pathology and tropical medicine, and in 1927 he was selected for specialist training He was employed on clinical and pathological duties at Halton from 1927 to 1931, including the investigation and control of an epidemic of cerebrospinal fever at Uxbridge in 1931 For his important contributions to preventive medicine he was awarded, in 1932, the Arnott gold medal of the Irish Medical Schools and Graduates Association From 1931 to 1933 he was pathologist to the R.A F in Iraq, but on his return to this country he switched over to physiology as applied to aviation medicine for two years before taking further appointments as pathologist at R A F hospitals in England

Early in 1939 he joined the medical directorate staff at the Air Ministry as a member of the hygiene department, and on the formation of the Flying Personnel Research Committee he was appointed secretary On the outbreak of war he became assistant director of hygiene, and for three years contributed much to the development of sound hygiene and sanitary practices at all R A F units at home and abroad During 1943 and 1944 he was the R A F principal medical officer in West Africa, and he was so successful in reducing the incidence of disease among personnel there that the occupied hospital bed-state was reduced ten-fold He was the first R A F medical officer to do the full Staff College course, and he graduated from it in 1946, with the highest marks

After the war, he was appointed director of hygiene and research at the Air Ministry, and he also served as chief executive officer of the Flying Personnel Research Committee until 1950, when he was promoted to deputy director-general of medical services In 1951 he became director-general His term of office came at a difficult period, for the R A F was being reorganised to streamline it to meet the changed concept of its functions, and, as the result of the Waverley Committee's recommendations, much had to be done to improve the career and emoluments of the medical officers, but Kilpatrick carried out the necessary changes efficiently and expeditiously

H E W writes

" James Kilpatrick was a most likeable man with considerable charm and courtesy He was quiet and unassuming, a characteristic which he maintained throughout his career, treating the most junior with every consideration Though a patient listener, he spoke his mind frankly and was firm in his decisions and actions He never deviated from what he considered to be his duty He was able, accurate, and shrewd both as a doctor and an administrator A deep thinker with a wide and practical knowledge of many subjects, he was a tower of strength on committees, expressing his views so clearly, concisely, and logically that he seldom failed to gain his point He had the confidence of all those who ever worked with him."

When he retired from the R.A F in 1957 he became dean of the London School of Hygiene and Tropical Medicine, and D D R writes.

"The transition from a Service hierarchy to the position of *primus inter pares* in an academic institution must have been difficult, but Sir James soon allayed any anxieties that might have arisen on this score. He was no martinet. Indeed, his administration of the school's affairs was distinguished by his gentle exercise of authority and his steadfast maintenance of both the dignity of his office and the warmth of his personal relationship with his colleagues With anyone who sought his advice or help he generously shared his wisdom, experience, and his time Students, coming as strangers to this country, must have been especially grateful for his kindly welcome.

"In 1958 he was elected president of the section of epidemiology and preventive medicine of the Royal Society of Medicine, and he brought to the conduct of the section's business the modesty, sincerity, and integrity which shone through all his actions, and the width of his outlook was reflected in his presidential address on the growth of the Royal Air Force medical branch as an organisation for prevention medicine

"He drove no-one hard except himself By his devotion to his duty he may well have cut short his term of office at the school. But in that span of time no man could have inspired more affection and respect than he did"

Sir James married in 1928 Marjorie, daughter of Charles Drean of Belfast, who survives him with two sons One is in the medical branch of the R.A.F and the other a medical student

The honours bestowed on him included appointment as honorary physician to the King in 1951, C.B in 1952, K.B.E in 1953, and the honorary LL.D of his alma mater in 1957

JOSEPH JEFFERSON COULTHARD

M.B Edin., F.R.C S.E

Dr Joseph Jefferson Coulthard, who died on March 29 at the age of 62, retired last year after practising in Edenbridge for 25 years

He qualified from the University of Edinburgh in 1922 and took the F.R.C.S.E. in 1930 For many years he was surgeon to the Edenbridge War Memorial Hospital, and of late years he had acted as anæsthetist Till 1958 he was chairman of the medical committee of the hospital His friends and patients gave him a presentation at the end of the late war, and on his retirement they gave him a scroll and a cheque, and a bronze plaque was placed in the hall of Edenbridge Hospital in recognition of the work he did there as well as for the town.

P H. M.-B writes "Dr Coulthard was a good sportsman and a fine shot and he fitted in well with the countryside he loved so well, so that he was known and esteemed beyond the borders of his own practice As he was a good judge of horses and dogs, he became a particular supporter of the Edenbridge annual show of which he was president in 1950, and thereafter he was patron as well as honorary medical officer He was also one of the founders and supporters of the particularly virile Edenbridge Medical Society His personal popularity, enriched by kindly witticisms, was immense and his visits to his more humble patients were often rendered more than ever welcome by the gift of a cock pheasant, or a brace of partridges He was much loved in the district and was always regarded as a special friend by rich and poor alike"

News

University of Oxford

Lord Adrian will give the Romanes lecture on May 24, at 5 P.M, in the Sheldonian Theatre. He will speak on factors in mental evolution

The George Herbert Hunt travelling scholarship for 1960 has been awarded to R. D Stedeford.

University of London

Dr C F Harris has been re-elected vice-chancellor of the university for 1960–61

Dr K W Cross, reader in physiology at St. Mary's Hospital Medical School, has been appointed to the chair of physiology at the London Hospital Medical College

Dr Cross qualified from St Mary's Hospital in 1940 After holding house-appointments at Hillingdon Hospital and St Mary's, he became deputy medical superintendent at Amersham E.M S Hospital He spent a year with the Friends' Ambulance Unit in China before he became lecturer in human physiology at St Mary's Hospital Medical School in 1947 He was appointed to the readership in the department in 1953 His published work includes papers on the respiration of the newborn

University of Durham

On July 1 the honorary degree of D.SC is to be conferred on Dr Donald Hunter

A postgraduate course on industrial health is to be held at the Medical School, King's College, Newcastle upon Tyne, 1, on Thursdays, from April 28 to June 16 at 2.30 P.M The speakers will include Lord Taylor, Dr. R. I McCallum, Dr G L Leathart, Prof R C Browne, Mr D N Walder, Mr P N Robson, Dr H G Miller, Prof J T Ingram, Dr J M L Howat, and Dr Sibyl Horner Further particulars may be had from the assistant registrar at the Medical School

University of Birmingham

The honorary degree of D SC is to be conferred on Sir Geoffrey Jefferson

Mr F C Walker has been appointed lecturer in surgery

University of Dublin

The following have been awarded the diploma in obstetrics

S Ahmed, S H M Logan, M L O Flaherty, T F Shaw

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting on April 4 with Mr Arthur Jacobs, the president, in the chair, the following were admitted to the fellowship

A C Arntzenius, C Chin Hin Chew Devappa Gowda Chinniah, J L. C Dall, M G Dunnigan, Ahmed Badr Eldin Sayed Ibrahim, J L J Ives, Julia A. Keane, A L. Linton, Shoukat Madmud Malik, Bhattarahalli Gururao Srinivasa Murthy, Iqbal Hussain Randhawa Allan Sinclair, W D Smith, R G Spector (qua physician), W M Borthwick, R J Scothorne (qua surgeon)

Hunterian Society

The subject for the 1960 essay competition for the gold medal of this society is the management of chronic arthritis in general practice. The competition is open to all general practitioners resident within the Commonwealth. Further details may be had from the hon secretary, Mr George Qvist, 72, Harley Street, London, W 1

South West Metropolitan Regional Hospital Board

The following have been awarded prizes in the board's 1959 competition

Consultants and S.H.M O.s—Mr Dermot Pierse and Dr H O'Donoghue (joint entry), Dr D Kendall

Senior registrars, registrars, and J.H.M O.s—Dr A Poteliakhoff, Dr P Sewell

Senior house-officers and house-officers—Dr J D Maynard, Dr C P Broad

Institute of Diseases of the Chest, London

Clinical demonstrations for doctors will be arranged by Dr J L Livingstone at the institute, in the grounds of the Brompton Hospital, Fulham Road, S W 3, on Fridays, at *5 P M from April 22 to July 8*

Midland Thoracic Society

The following officers and council members have been elected for the 1960–61 session

President, Dr G R W N Luntz hon secretary, Dr H E Thomas, council, Dr A O Bech, Dr B T Davis, Dr A W B Macdonald, Dr S Z Kalinowski

C H Milburn Prize

This prize (£100) for an essay or study on forensic medicine is offered for the first time this year Any doctor may enter Further particulars may be had from the secretary of the British Medical Association, B M A House, Tavistock Square, London, W C 1

Feeding of Antibiotics to Farm Animals

The Agricultural and Medical Research Councils have set up a joint committee to examine the possible consequences of the feeding of antibiotics to farm animals and to consider whether this practice constitutes any danger to human or animal health Lord Netherthorpe is to act as chairman, and Prof A A Miles has agreed to take the chair of a scientific sub-committee which will examine the evidence in detail and place its findings before the main committee

Current Trends in Cardiology

The Chest and Heart Association will hold a symposium on this subject at 1, Wimpole Street, London, W 1, on Wednesday, June 8, at 3 30 P M The speakers will be Dr K Shirley Smith, Dr Maurice Campbell, Dr G W Hayward, Dr Frances Gardner, Dr Walter Somerville, and Dr J N Mickerson Further particulars and tickets (25*s*) may be had from the association, Tavistock House North, W C 1

First British Congress on the History of Medicine and Pharmacy

This congress, organised by the faculty of the history of medicine and pharmacy at the Society of Apothecaries of London, in cooperation with the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Royal Society of Medicine, will be held in London, on Sept 29 and 30 Further particulars may be had from Dr F N L Poynter, Wellcome Historical Medical Library, Wellcome Building, Euston Road, N W 1

E E G and Clinical Neurophysiology in Pædiatric Problems

The Institute of Child Health is holding a course on this subject on Saturday and Sunday, June 18 and 19, at The Hospital for Sick Children, Great Ormond Street, London, W 1 The speakers will be Dr Otto Magnus (Wassenaar, Holland), Dr J A V Bates, Prof H L Teuber (New York), Dr R Rudel (New York), Dr P B Bradley, Dr Giuseppe Pampiglione, and Dr J A Simpson Further particulars may be had from Dr G H Newns, at the institute

Leverhulme Trust Fund

The third report of this Trust—which is to be the first of a series of triennial reports—covers 1956 to 1958 During these years the Trust allocated £593,000, of which almost a third was given to medical research

Grants include £9100 to the Institute of Laryngology and Otology, London, for research fellowships, £35,000 to the Middlesex Hospital Medical School, London, for scholarships at the Institute of Clinical Research, £10,700 to the Mental Health Research Fund for research fellowships, £9500 to St Mary's Hospital Medical School London, for biochemical research, £58,100 to the Royal College of Surgeons of England for research fellowships in dental surgery, anæsthetics, physiology, and for general research, £14,000 to the London School of Hygiene and Tropical Medicine for research in industrial medicine

British Diabetic Association

A medical and scientific section of this Association has been set up, with Prof F G Young, F R S, as chairman and Dr J M Stowers and Dr D A Pyke as hon secretaries Inquiries about membership should be sent to the Association, 152, Harley Street, London, W 1

International Federation of Surgical Colleges

A meeting of the Federation is to be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2, from Oct 18 to 20 The theme of the meeting is to be the training of surgeons

---

Postgraduate demonstrations in psychiatry and neurology will be given at St George's Hospital Medical School, London, S W 1, at 5 P M on Thursdays, from April 28 to June 16

At a meeting of the Medical Society of the Roehampton Plastic Centre on Thursday, April 28, at 8 P M, at the centre, London, S W 15, Mr Guy Pulvertaft will speak on advances in hand surgery

Copies of the *Digest of Statistics of Incapacity* for 1956–57 can now be had from the statistics division of the Ministry of Pensions and National Insurance, 1, Adam Street, London, W C 2

Copies of a new British standard for hospital pressure sterilisers for water (B S 3213 1960) may be obtained (6*s* each) from the British Standards Institution, Sales Branch, 2, Park Street, London, W 1

RESEARCH SCHOLAR

R. Kilpatrick
M.B. Edin., M.R.C.P.E.
LECTURER IN PHARMACOLOGY

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS,
UNIVERSITY OF SHEFFIELD

Recently there has been much interest in new sulphonamides which produce persistently high blood-levels with a single daily dose. These concentrations are comparable to those produced by the established regime of giving sulphadimidine every six hours.

Two long-acting sulphonamides of this type are sulphaphenylpyrazole ('Orisulf') and sulphamethoxypyridazine ('Lederkyn'). Experimentally it was found that they were only slowly acetylated and that they penetrated little into cerebrospinal fluid (Rentchnick 1958). Though in-vitro these compounds had similar antibacterial activity to sulphadiazine, some of the results of clinical trials were disappointing (Harris et al. 1957, Prlina et al. 1958). Better results were claimed when larger doses were used (Walker and Hambukger 1957, Grieble and Jackson 1958, Jefferson 1958). These features of lengthy action, slow acetylation, poor penetration, and possibly inferior therapeutic activity suggested the present study on the degree to which these new sulphonamides were attached to plasma-proteins, and the effect of any such binding on their persistence in the blood, antibacterial action, and penetration into tissue-fluids. The compounds studied were sulphaphenylpyrazole, sulphamethoxypyridazine, and sulphachloropyridazine. This last compound was included because of its close chemical similarity to sulphamethoxypyridazine, and because the duration of its action is brief (Jones et al. 1957). These compounds were compared with two well-established compounds—sulphadimidine and sulphadiazine.

Methods

Chemical Estimation of Sulphonamides

This was based on the method of Bratton and Marshall (1939), in which napthyl-ethylene-diamine-dihydrochloride is used as the coupling agent to produce the colour. Optical densities were measured in a 'Spekker Absorptiometer' H 760.301. These were converted to sulphonamide concentrations using calibration lines prepared by adding sulphonamide to plasma or urine. This was necessary as the recovery varied with the fluid analysed. Blank readings were deducted as some colour was often produced in urine before any sulphonamide was given. Free sulphonamide was estimated, and then total sulphonamide by hydrolysing plasma or urine with 0·01 *N* hydrochloric acid at 100°C for sixty minutes. The difference between these estimations represented the amount of acetylated sulphonamide.

Protein-binding of Sulphonamides

The degree of attachment of sulphonamides to protein was measured by dialysing human plasma to which sulphonamide had been added, against phosphate buffers. Aseptic technique was used in separating the plasma and in constructing the dialysis units, to prevent the growth of microorganisms during equilibration. Each unit was a sac of Visking dialysis tubing, containing 10 ml. of phosphate buffer within a 25 ml. screw-capped container, and the whole was sterilised by autoclaving. After cooling, 10 ml. of plasma containing varying concentrations of sulphonamide was added around each sac. The units were agitated for twelve hours at 37°C, to allow equilibration of the diffusible constituents between plasma and buffer. Sulphonamide concentrations were then estimated in outer and inner fluids. The concentration of diffusible sulphonamide was given by the concentration within the sac, whereas in the outer fluid there was both diffusible and protein-bound sulphonamide. In calculating the results, allowance for space occupied by protein in plasma-water was made, as suggested by Davis (1942).

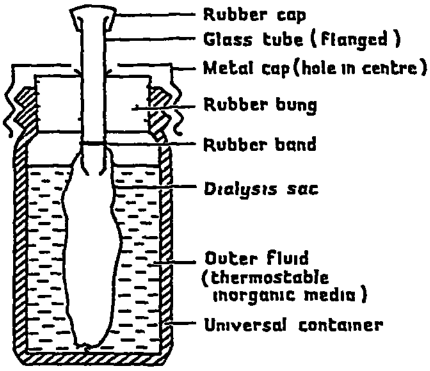

Fig. 1—Dialysis unit used for preparing sterile media to determine antibacterial activity of protein-bound sulphonamide.

Acetylation Site in the Liver

Acetylation-rate was measured by perfusing sulphonamide through isolated rabbit liver. The liver was perfused at a constant rate of 140 ml. per minute through a cannula in the portal vein, and the system was maintained at 37°C. A constant level in the upper reservoir was maintained by a Dale Schuster pump, which returned the perfused fluid from the lower reservoir. Oxygenation was effected by spraying the returning perfusate in an atmosphere of oxygen on to the walls of the upper reservoir. Samples of the perfusion fluid were withdrawn at intervals and analysed for free and total sulphonamides.

Antibacterial Action and Protein-bound Sulphonamide

This was measured by comparing the growth of a strain of *Staphylococcus aureus* in two media identical in diffusible constituents but only one of which contained protein. Minimal bacteriostatic concentrations of various sulphonamides were then measured using these two media. The media were prepared using a dialysis unit (fig. 1) which could easily be assembled and dismantled aseptically. To each unit, 10 ml. of basic inorganic salts was added on the outside of the dialysis sac. These salts were thermostable and were sterilised by heating at 115°C for thirty minutes. Further salts were necessary for growth, but, as precipitation occurred on heating, they were sterilised individually and then added to sterile human plasma (table I). 10 ml. of this fortified plasma was

TABLE I—COMPOSITION OF BACTERIOLOGICAL MEDIA BEFORE DIALYSIS

Medium	Constituent	Amount	Sterilisation
Basic inorganic	KH_2PO_4 $(NH_4)_2SO_4$ NaOH Distilled water	6·8 g 1·0 g To desired pH To 1000 ml	Sterilised at 115°C for 30 min. in autoclave
Plasma	$MgSO_4$ $CaCl_2$ $FeSO_4$, $7H_2O$ Glucose Sterile human plasma	10·72 mg in 0·5 ml 20·0 mg in 0·5 ml 1·0 mg in 0·5 ml 5·0 g in 10·0 ml To 1000 ml	Aqueous solution sterilised individually and added to plasma aseptically

injected into each sac, and the sacs were agitated at 37°C for twelve hours Larger volumes of inner and outer fluids were obtained by pooling Increasing concentrations of various sulphonamides were then prepared in each fluid by adding 0·5 ml of sulphonamide solutions of different concentrations to 4·5 ml of fluid Each tube was inoculated with 0·18 million organisms from a diluted twenty-four-hour culture of *Staph aureus*, and incubated at 37°C overnight The inoculum size was critical because, if too many organisms were initially introduced, it was difficult to determine the minimum bacteriostatic concentration by a plating technique Growth in both media was assessed by measuring changes in pH and the ability of a loopful to produce colonies on an agar plate Clot formation was noted in the dialysed plasma, and dialysed non-proteinous fluid was examined for turbidity Protein-binding of sulphonamide in the plasma was measured as already described The particular strain of *Staph aureus* chosen was inhibited by concentrations of sulphonamides which could readily be achieved in the blood-stream by therapeutic doses Preliminary experiments showed that human plasma had no direct inhibiting action on the growth of this organism

Results

Plasma Levels in Rabbits and Man

Concentrations of free and conjugated sulphonamide were measured in rabbits following 50 mg of various sulphonamides given orally or intravenously (table II) *Sulphadimidine* was cleared within six hours and sulphamethoxypyridazine within twelve hours Sulphaphenylpyrazole persists very long in rabbits, being still detectable after seventy-two hours In man these relative durations are different (table III) When 1 g of each sulphonamide was given one hour before breakfast it was found that sulphadimidine was cleared within twenty-four hours, whereas sulphamethoxypyridazine was detectable after seventy-two hours Sulphaphenylpyrazole was of intermediate duration, being cleared within forty-eight hours The slow rate of acetylation of these two long-acting sulphonamides was striking in comparison with the rapid acetylation of sulphadimidine Sulphachloropyridazine disappeared from the blood as rapidly as sulphadimidine, even though it is chemically very similar to sulphamethoxypyridazine, but, unlike sulphadimidine, it was slowly acetylated

TABLE IV—PLASMA AND CEREBROSPINAL-FLUID CONCENTRATIONS OF SULPHONAMIDE IN MAN

Compound	Dose (g) by mouth	Time interval between dose and samples (hr)	Concentration of free sulphonamide (mg per 100 ml)	
			Plasma	C.S.F.
Sulphaphenylpyrazole	1	5·0	4·6	0
	1	6·5	12·2	0
	1	7·5	6·7	0
	1	19·0	3·7	0
	1	19·5	0·5	0
	1	20·5	2·2	0
	1	22·0	0·8	0
Sulphamethoxypyridazine	1	6·0	10·0	0·7
	1	19·0	5·2	0·4
	1	20·0	4·6	0·4
	2	8·0	12·0	0·8
	2	8·0	15·5	1·3
Sulphadimidine	1	6–8	0·9	0·3
	1	6–8	3·4	0·5
	1	6–8	4·0	0·5
	1	6–8	1·5	0·6
	1	6–8	7·0	1·2
	1	6–8	7·8	1·2
	3	6–8	14·5	1·6

Urine analyses from these experiments confirmed the above results on duration of the drugs in the body and the extent of acetylation

Concentration in Cerebrospinal Fluid

The degree of penetration of these sulphonamides into cerebrospinal fluid was measured following varying doses The lumbar puncture, which was a diagnostic procedure in these patients, was performed between four and twenty-four hours after the dose The protein concentration of all these lumbar fluids was normal Sulphadimidine penetrated more readily than sulphamethoxypyridazine, as it was found in higher concentrations in the cerebrospinal fluid with similar plasma levels (table IV) Sulphaphenylpyrazole was not detected in cerebrospinal fluid even though high plasma levels were achieved and adequate time was allowed for diffusion

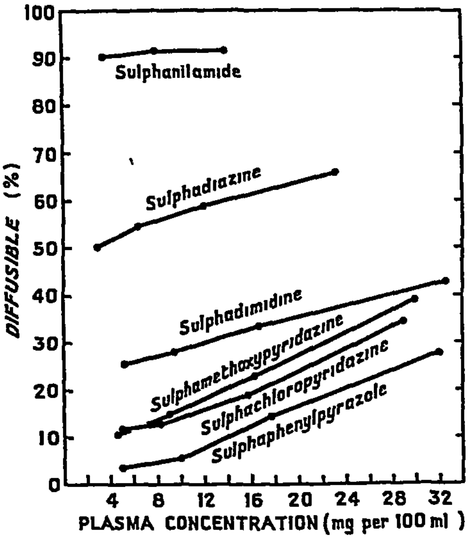

Fig 2—Effect of increasing concentration of various sulphonamides on binding of sulphonamide to plasma-proteins at pH 7·4.

Degree of Protein-binding

All the new sulphonamides were more extensively bound to plasma-protein than sulphadimidine. This applied to plasma from both rabbits and man (fig 2). Sulphaphenylpyrazole was bound to the greatest extent. The degree of attachment to plasma-proteins varied with both pH and concentration of sulphonamide. There is a striking increase in binding as pH changes from acidity to alkalinity, and this increase is greater with the less extensively bound compounds (fig 3). It is therefore most important to control the pH when performing binding experiments. Degree of protein-binding decreases with increasing concentration of sulphonamide (fig 2).

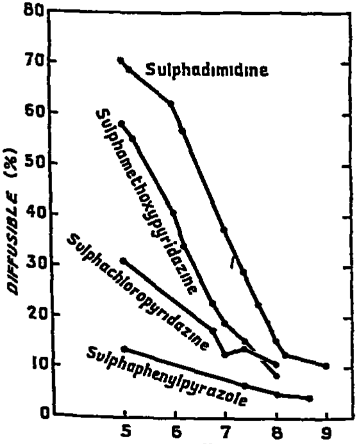

Fig 3—Effect of pH on binding of sulphonamide to plasma-proteins at sulphonamide concentration of 10 mg per 100 ml.

A concentration of 10 mg sulphadimidine per 100 ml plasma is commonly regarded as a satisfactory therapeutic level. This produces a diffusible concentration of 2·9 mg per 100 ml, which has accordingly been used as a reference standard. The total concentration of the various sulphonamides required to produce this diffusible level is shown in table V. The new sulphonamides had to be present in higher total concentration. In the case of sulphaphenylpyrazole the total plasma concentration necessary was nearly twice that of sulphadimidine.

Acetylation and Protein-binding

Acetylation of each sulphonamide was measured by perfusing rabbit liver with the drug dissolved in dialysed non-proteinous fluid obtained as in the protein-binding experiments. The rate of acetylation was measured until the rate slowed. Dialysed plasma containing the same concentration of sulphonamide was then perfused, and the rates of acetylation were compared. The initial rate varied with each liver, but after plasma perfusion a final perfusion without plasma was done, and the initial rate was always regained (figs 4 and 5). Plasma had no effect on the acetylation-rate of sulphadimidine but produced a reduction with sulphamethoxypyridazine and sulphachloropyridazine. The most striking slowing of acetylation-rate in the presence of plasma was found with sulphaphenylpyrazole. This order of effect agrees with the degree of protein-binding of these compounds.

Antibacterial Activity of Protein-bound Sulphonamide

An example of an antibacterial experiment is shown in fig 6. The concentration of sulphamethoxypyridazine in dialysed non-proteinous fluid required to inhibit growth is within the range 5×10^{-5} mol and 10×10^{-5} mol, whereas in dialysed plasma it is between 35 and 40 $\times 10^{-5}$ mol. However, the latter range in plasma gave diffusible concentrations which were similar to the minimal bacteriostatic concentration of the dialysed non-proteinous fluid. The higher concentration of sulphonamide required with each particular compound in the presence of plasma always equalled the amount that was bound to protein. The results with the other compounds are shown in table VI, where there is evident agreement between minimum bacteriostatic concentration without plasma and the concentration of diffusible sulphonamide when plasma was present. It should be emphasised that minimal bacteriostatic concentrations for the various compounds cannot be directly compared. The experiments with each sulphonamide were done on separate days and no attempt was made to compare the relative antibacterial activity of these sulphonamides in the absence of protein.

TABLE V—PLASMA CONCENTRATIONS OF SULPHONAMIDES REQUIRED TO PRODUCE THE SAME DIFFUSIBLE CONCENTRATION

Sulphonamide	Plasma concentration (mg per 100 ml) necessary to produce a diffusible concentration of 2·9 mg per 100 ml
Sulphaphenylpyrazole	18·6
Sulphamethoxypyridazine	14·0
Sulphachloropyridazine	15·5
Sulphadimidine	10·0
Sulphadiazine	5·5

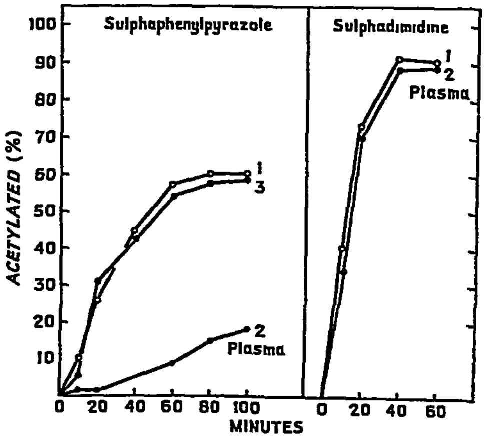

Fig 4—Effect of plasma on rate of acetylation of sulphaphenylpyrazole and sulphadimidine

Rabbit liver perfused in order with sulphonamide contained in non-proteinous fluid (1), plasma (2), and non-proteinous fluid (3)

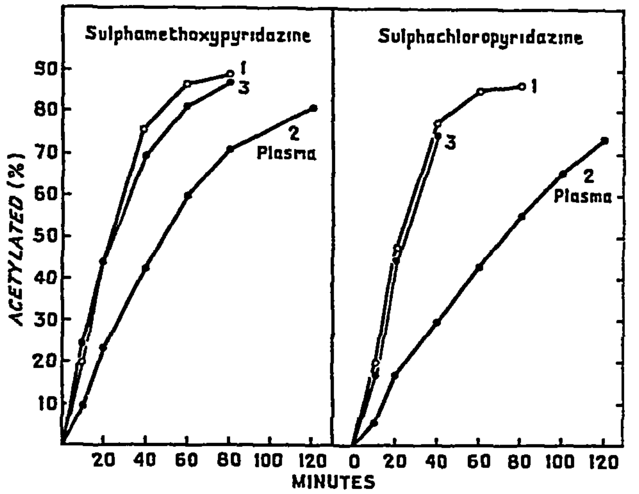

Fig 5—Effect of plasma on rate of acetylation of sulphamethoxypyridazine and sulphachloropyridazine

Rabbit liver perfused in order with sulphonamide contained in non-proteinous fluid (1), plasma (2), and non-proteinous fluid (3).

Antibacterial Activity of Sulphaphenylpyrazole in Man

8 patients with urinary-tract infections were studied. 5 had acute cystitis or pyelonephritis, and 3 had chronic urinary infection. In each case the causal organism was sensitive initially to less than 100 µg. of sulphonamide on a paper disc. The patients were given 2 g. of sulphaphenylpyrazole on the first day and then 1 g. daily for ten days. This produced plasma concentrations between 5 and 10 mg. per 100 ml. for most of the time and at least 50 mg. per 100 ml. of free sulphonamide in urine. This therapy did not produce disappearance of organisms or leucocytes from the urine in any patient. 2 of the patients with acute infection had some temporary improvement in symptoms. After the treatment 4 patients were successfully treated with sulphadimidine. Organisms from 2 of the remaining 4 cases had become resistant to sulphonamide, and all 4 were successfully treated with antibiotics.

Discussion

Previous attempts have been made to measure the degree of attachment of sulphonamide to plasma-protein (Davis 1942). Much less information is available concerning the antibacterial activity of sulphonamide bound to human plasma. Anton (1959) found that sulphonamide bound to bovine albumin had no antibacterial activity. It is clear from the present results that some of the new sulphonamides are bound to plasma-protein to a much greater extent than sulphadimidine or sulphadiazine, and that bound sulphonamide is not active against bacterial growth. Bacteria usually multiply in tissue planes, and the tissue-fluid concentration of sulphonamide will be similar to the diffusible plasma concentration. Thus, with extensive protein-binding, small tissue-fluid concentrations would be expected and the small amounts of sulphamethoxypyridazine and sulphaphenylpyrazole found in cerebrospinal fluid are a reflection of this (Boger 1959). The poor penetration of sulphaphenylpyrazole into cerebrospinal fluid was observed by Rentchnick (1958), but he found high concentrations in patients with meningitis. These might, however, be due to the passage of inactive protein-bound sulphonamide, as the protein concentration of the fluid increases in meningitis.

It is the usual practice to compare in-vitro antibacterial activities of sulphonamides in media containing either low concentrations of protein or no protein at all. Comparisons in such media have shown that the new sulphonamides have similar antibacterial activities to sulphadiazine (Harris et al. 1958, Niepp et al. 1958). The generally recommended doses of the new sulphonamides were chosen to give total plasma concentrations similar to those considered adequate for therapy with sulphadiazine and sulphadimidine. Much lower tissue concentrations will result, and antibacterial activity will thus be less. This may account for the poor results in urinary infections with 1 g. daily doses of sulphaphenylpyrazole and for the results of Harris et al. (1957) and Prlina et al. (1958) with 0·5 g. daily doses of sulphamethoxypyridazine.

TABLE VI—RELATIONSHIP BETWEEN DIFFUSIBLE SULPHONAMIDE CONCENTRATION, MINIMUM BACTERIOSTATIC CONCENTRATION IN PLASMA, AND MINIMUM BACTERIOSTATIC CONCENTRATION IN NON-PROTEINOUS FLUID (pH 7·0)

Sulphonamide	Diffusible sulphonamide concentration as percentage of minimum bacteriostatic concentration in plasma	Minimum bacteriostatic concentration of sulphonamide in non-proteinous fluid as percentage of the minimum bacteriostatic concentration in plasma
Sulphaphenylpyrazole	10–12	10–16
Sulphamethoxypyridazine	18·5–20·5	14·3–25
Sulphachloropyridazine	11·3–15·0	9·0–16·6
Sulphadimidine	39·2–39·6	36·3–41·6

The rate of acetylation of sulphonamides is also obviously related to the degree of protein-binding. These new sulphonamides are acetylated at much lower rates than sulphadimidine, and this is a useful feature, as acetylated sulphonamide has no antibacterial activity but retains toxic properties. Unfortunately the slow acetylation-rates are produced by the same mechanism which reduces the tissue-fluid concentration.

The mechanism of the delayed excretion and hence maintained plasma concentrations of the sulphaphenylpyrazole and sulphamethoxypyridazine is not yet defined. Clearly it is not directly related to protein-binding since sulphachloropyridazine is quickly excreted and yet

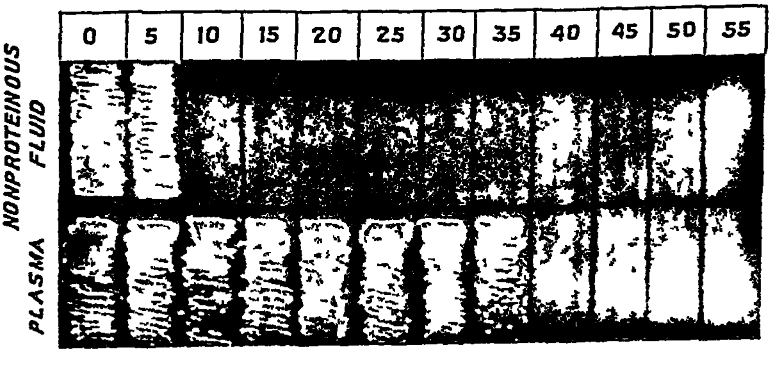

Fig 6—Determination of minimum bacteriostatic concentration of sulphamethoxypyridazine by plating technique showing effect of sulphamethoxypyridazine in plasma and non-proteinous fluid on growth of *Staph aureus* at pH 7 (concentrations given in mol.×10⁻⁵)

bound to protein to a greater extent than sulphamethoxypyridazine. Differential renal handling probably accounts for their slow excretion. There is also a striking species difference in excretion as the excretion-rates for sulphaphenylpyrazole and sulphamethoxypyridazine were reversed in rabbits and man. Thus this animal is unsuitable for screening new sulphonamides, particularly with respect to prolonged plasma levels.

Our results suggest that the therapeutic value of these new sulphonamides does not surpass that of the older compounds. It seems likely that for successful therapy with these highly protein-bound sulphonamides greater plasma concentrations will be required than are necessary with sulphadimidine or sulphadiazine. Toxic effects with these newer drugs have already been described (Holsinger et al. 1958, Lindsay et al. 1958, Schwartz and Norton 1958), and if larger doses have to be employed for therapeutic activity the patient may be exposed to a greater risk than that associated with sulphadimidine.

Summary

New long-acting sulphonamides, such as sulphaphenylpyrazole and sulphamethoxypyridazine, are more extensively bound to plasma-protein than the older sulphonamides, such as sulphadimidine and sulphadiazine.

Extensive protein-binding leads to lower plasma diffusible concentrations and therefore lower concentration in compartments such as cerebrospinal fluid.

Antibacterial activity depends on diffusible concentration of sulphonamide. Protein-bound sulphonamide has no antibacterial activity. Acetylation-rates also depend on diffusible concentration, and thus highly protein-bound sulphonamides are only slowly acetylated.

Rate of renal excretion does not depend solely on protein-binding since sulphachloropyridazine, which is highly protein-bound, is nevertheless rapidly eliminated in the urine.

Higher total plasma concentrations are required with the newer sulphonamides than with the older ones, to produce similar diffusible concentrations and similar therapeutic effect. These higher plasma concentrations may increase the liability to toxic effects.

This work was done during tenure of a scholarship given by Ciba Laboratories Ltd. to one of us (B. B. N.). We would like to thank Dr. M. Mackay and Dr. E. K. Blackburn for supply of human plasma, Mr. A. A. Jefferson, Dr. F. T. Thorpe, and Dr. G. E. Fenton for help in obtaining specimens of cerebrospinal fluid, Dr. J. K. A. Beverley for advice and assistance in the bacteriological experiments, and Prof. G. M. Wilson for advice and encouragement.

LATE EFFECTS OF LUMBAR SYMPATHECTOMY

ON BLOOD-FLOW IN THE FOOT IN OBLITERATIVE VASCULAR DISEASE

J. A. GILLESPIE
M.D., Ch.M. St. And., F.R.C.S.
LECTURER IN SURGERY,
UNIVERSITY OF ST. ANDREWS, DUNDEE *

WHILE the effect of sympathectomy on blood-flow has often been investigated in non-occlusive vascular disease, especially in the upper limb, there have been no extensive investigations of its long-term effects in patients with obliterative vascular disease of the lower limb. Of particular importance is the effect on blood-flow in the foot, since the prime indication for sympathectomy today is an ischæmic foot in a limb not suitable for some form of direct arterial surgery. In this paper I present the results of blood-flow measurements in all the available surviving, non-amputated, members of a consecutive series of 100 patients sympathectomised between one and seven years previously for obliterative vascular disease. As rather more than half the patients were operated on by me, and the remainder by one other surgeon, the technique of operation was fairly uniform.

The findings of the clinical review are fully dealt with elsewhere (Gillespie 1960a). 25 patients were dead, 8 survivors had had a major amputation, and 2 patients were untraced. Of the remaining 65, 61 were fit enough and

willing to attend for blood-flow investigations. The measurements made can thus fairly be said to reflect the average long-term effect of sympathectomy on foot blood-flow in patients with obliterative vascular disease.

For comparison, blood-flows were also measured in 18 of a consecutive series of 20 patients sympathectomised for non-obliterative disease between one and seven years previously.

Methods

Blood-flows were measured by venous occlusion plethysmography (Barcroft and Swan 1953) in a thermostatically controlled laboratory at 22°C, using water-filled plethysmographs kept at a constant temperature of 32–34°C. The collecting cuff pressures used were those yielding the maximum inflow curves; owing to the arterial occlusions they were necessarily lower than the pressures normally used. The basic resting blood-flow in the feet was recorded at half-minute intervals over a ten-minute period, after the patient had been allowed to settle for twenty minutes following fitting of the plethysmographs. Thereafter, vigorous body heating (Pickering and Hess 1933) was applied by a heat cage over the chest and head for at least twenty minutes, prolonged if necessary till the patient was sweating freely and his oral temperature had risen at least 0·3°F, and usually much more. Flows were then again recorded over a ten-minute period.

Blood-flows were calculated in millilitres per 100 ml. of foot per minute. The mean post-heating flow was expressed as a percentage increase or decrease of the mean pre-heating or resting flow (Barcroft and Hamilton 1948a and b). This change constituted the "vasomotor test".

In all, the vasomotor test was carried out in 75 limbs sympathectomised for obliterative arterial disease, and in 26 sympathectomised for non-obliterative disease. Flows were also measured in the non-sympathectomised limbs of those patients with a unilateral sympathectomy.

Results and Discussion

Duration of Effect of Lumbar Sympathectomy

In considering the duration of effect of lumbar sympathectomy on blood-flow one must clearly distinguish between the early falling off in the maximal flows recorded a few hours after operation (Lynn and Barcroft 1950) and the long-term effect on blood-flow. This investigation is concerned only with the latter.

46 of the patients available for blood flow-measurements had had a unilateral sympathectomy for obliterative disease. It was thus possible to compare the resting blood-flows in the sympathectomised and non-sympathectomised feet of these patients between one and seven years after operation (table I). In 38 (83%) of the 46 patients the resting blood-flow in the sympathectomised foot exceeded that in the non-sympathectomised foot, the average flow being nearly twice as great. That is, double the amount of blood was still flowing through these feet sympathectomised for obliterative vascular disease between one and seven years previously.

This figure probably underestimates the effect of sympathectomy on blood-flow in the foot, for two reasons. Firstly, if flows had been measured under normal cool environmental conditions, instead of in a warm laboratory, then vasoconstriction in the normal foot would have made the difference in flows even greater. Secondly, the resting foot blood-flow in untreated limbs with occluded arteries is often less than in more normal limbs. This is illustrated by table II, which sets out the results of blood-flow measurements in the feet of 15 untreated patients in whom aortography had demonstrated a complete arterial occlusion in one limb, the other limb being relatively free from atherosclerosis. In every patient, except 1 in whom flows in the two feet were equal, blood-flow in the foot of the occluded limb was less than in its more normal fellow. The mean foot flow in the 15 least affected limbs was 1·7 times greater than that in the occluded limbs. It therefore follows that a postsympathectomy increase of blood-flow in the occluded limbs to twice as much as that in the more normal limbs probably means that the preoperative flow has been trebled or quadrupled.

TABLE IV—EFFECT OF TIME ON THE RESTING BLOOD-FLOW IN FEET OF 46 PATIENTS WITH UNILATERAL SYMPATHECTOMY FOR OBLITERATIVE DISEASE

Interval between operation and testing (years)	Type of limb	No. of limbs	Foot blood flow (ml. per 100 ml. per min.)	
			Mean	Range
1–7	Sympathectomised	46	3·6	1·2–9·7
	Non-sympathectomised	46	2·2	0·8–5·0
1–2	Sympathectomised	19	3·4	1·2–6·2
	Non-sympathectomised	19	2·3	0·8–4·3
2–7	Sympathectomised	27	3·8	1·5–9·7
	Non-sympathectomised	27	2·1	1·0–5·0

For comparison with the results in obliterative disease, blood-flows were also measured in 10 patients who had had a unilateral sympathectomy for non-obliterative disease between one and seven years previously (table III). In 9 the flow in the sympathectomised foot exceeded that in the non-sympathectomised foot by a mean of 3·3 times. The difference between the mean of 2·0 in the obliterative-disease group and this of 3·3 is undoubtedly in part a result of the obliterative disease process in the former, but may also partly be explained by the fact that in non-obliterative disease the resting flows in the two feet before operation are equal.

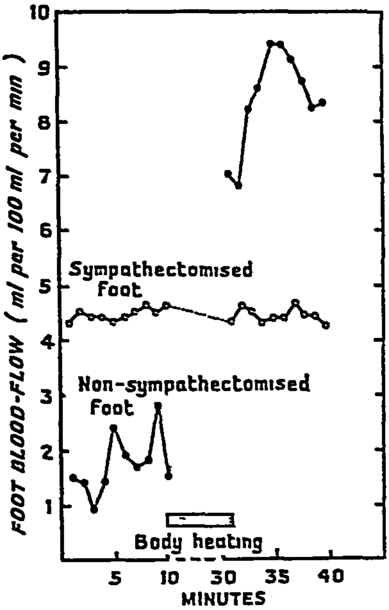

Fig. 1—A negative vasomotor test

The patient had had a unilateral sympathectomy for non-obliterative disease 15 months previously There is no rise in flow in the sympathectomised foot after body heating, while there is a large rise in the non-sympathectomised foot

To determine whether with the passage of time the effect of a sympathectomy becomes less, it is of interest to compare the interval between operation and measurement of blood-flows with the mean difference between the flows in the sympathectomised and non-sympathectomised feet. This has been done for the 46 patients of the obliterative disease group considered as a whole, irrespective of whether flows were larger or smaller in the sympathectomised foot at the time of testing (table IV) The mean flow in all the sympathectomised feet was 3 6 ml per 100 ml foot per minute, compared with 2 2 ml in the non-sympathectomised feet, the difference in flows being significant (at the 0 1% level) In those patients in whom the interval between operation and testing was between one and two years, the mean flow in the sympathectomised feet was 3 4 ml compared with 2 3 ml. in the non-sympathectomised feet Where the interval was two or more years, the similar figures for mean flow were 3 8 and 2 1 ml respectively The difference between the means at the two intervals is not significant statistically There is thus no evidence that the effect of sympathectomy on blood-flow in the foot diminishes with the passage of time, at least between one and seven years after operation

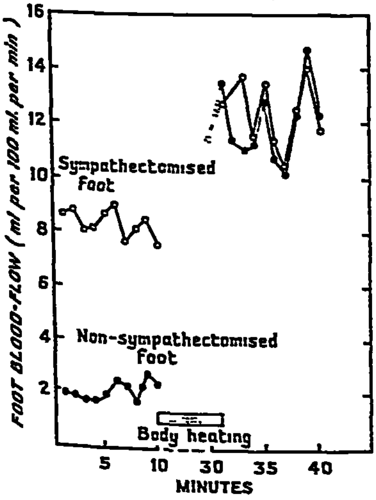

Fig 2—A positive vasomotor test.

The patient had had a unilateral sympathectomy for non-obliterative disease $4\frac{1}{2}$ years previously There is a rise in flow in the sympathectomised foot, as well as in the non-sympathectomised foot, after body heating

This part of the work can be summarised by stating that lumbar sympathectomy produces a lasting and important increase in blood-flow in the foot, even in obliterative vascular disease.

Evidence of Some Recovery of Vasomotor Activity

Even though a lasting doubling or trebling of blood-flow in the foot follows lumbar sympathectomy, there may be partial recovery of sympathetic vasomotor activity The greater this recovery, the less efficacious will operation remain in preventing reflex vasoconstriction in the foot.

To determine how much recovery of sympathetic vasomotor activity did occur, the body heating test already described was employed The principle of the test is that, if there is any recovery of sympathetic vasomotor activity, then on vigorous body heating this activity is abolished, and blood-flow in the sympathectomised foot increases The results of a negative vasomotor test are illustrated in fig 1 The resting flow in the sympathectomised foot is two or three times greater than in the other foot. After body heating, flow is increased fivefold in the normal foot, but remains unchanged in the sympathectomised foot. There is thus no evidence of any return of sympathetic vasomotor activity in this patient A positive vasomotor test is illustrated in fig 2 Here, flows in both the sympathectomised and normal feet increased with body heating, showing that there had been some recovery of vasomotor activity This recovery is far from complete, however, since the resting flow in the sympathectomised foot was still four times greater than in the other

These two patients had been sympathectomised, respectively fifteen months and four and a half years previously, for non-obliterative disease. Their vessels were fully capable of dilatation on body heating Positive tests, however, are also readily obtained in obliterative disease where there has been some recovery of sympathetic vasomotor control The results of the vasomotor test are set out in table v for the 61 patients sympathectomised for obliterative arterial disease. In making up the table only increases in blood-flow on body heating of more than 10% have been regarded as significant. Of the 75 sympathectomised limbs in these patients, 8 showed a rise in blood-flow in the foot after body heating That is, in only 11% of these limbs was there evidence of late partial recovery of sympathetic control

TABLE V—EFFECT OF BODY HEATING ON BLOOD-FLOW IN SYMPATHECTOMISED AND NON-SYMPATHECTOMISED FEET OF 61 PATIENTS OPERATED ON FOR OBLITERATIVE DISEASE

—	Blood-flow not increased in	Blood-flow increased in
75 sympathectomised limbs	67 limbs	8 limbs (11%)
46 non-sympathectomised limbs	10 limbs	36 limbs (78%)

It might be argued, however, that this low figure is due not to an absence of vasomotor activity but to inability of the vessels to dilate with body heating, owing to disease. It is impossible to say how far this is so, but two observations suggest that the figure is not excessively low Firstly, although the disease process was so often bilateral, with absence of pulses in both legs, 78% of the non-sympathectomised feet of the patients with a unilateral sympathectomy for obliterative disease showed significant vasodilatation on body heating Secondly, the figure of 11% compares well with that of 12% obtained when the body heat test was applied in 18 patients sympathectomised between one and seven years previously for non-obliterative disease (table VI) Of the 26 sympathectomised feet of these patients only 3 (12%) showed evidence of a significant return of vasomotor activity, although their vessels had a normal capacity for dilatation

This low rate of recovery of sympathetic activity in the foot (11 or 12%) is particularly striking when compared

TABLE VI—EFFECT OF BODY HEATING ON BLOOD-FLOW IN THE SYMPATHECTOMISED AND NON-SYMPATHECTOMISED FEET OF 18 PATIENTS OPERATED ON FOR NON-OBLITERATIVE DISEASE

—	Blood-flow not increased in	Blood-flow increased in
26 sympathectomised limbs	23 limbs	3 limbs (12%)
10 non-sympathectomised limbs	0	10 limbs (100%)

with that in the hand after cervicodorsal sympathectomy Barcroft and Hamilton (1948a and b), for example, found that in 78% of hands tested between one and six years after operation there was evidence of recovery The incidence of vasomotor recovery in the lower limb is also much lower than that of sudomotor recovery (Gillespie 1960b)

It is of interest that even where there was some significant recovery of vasomotor activity, the increase in blood-flow on body heating seldom exceeded 50% (table VII), and the resting flow had always remained higher in these limbs than in the non-sympathectomised limbs

It will be noted that blood-flow in the sympathectomised feet frequently became less after body heating In the absence of any recovery of vasoconstriction tone, which would be released on body heating to give an increase in flow, this is not surprising When generalised vasodilatation is produced by body heating, or by a vasodilator (Gillespie 1959), blood is diverted from the sympathectomised limb into the widespread new areas of reduced peripheral resistance—an example of De Bakey's hæmametakinesia, or " borrowing-lending " phenomenon (De Bakey et al 1947)

Practical Importance of the Increased Blood-flow

As already stated, the value of lumbar sympathectomy in obliterative vascular disease is in the treatment of ischæmic skin lesions in patients in whom, for one reason or another, direct arterial surgery cannot be applied The lasting doubling of blood-flow in the foot which occurs on an average is likely to be important in the healing of existing skin lesions and the prevention of future ones While 11% of limbs may show some late recovery of vasomotor activity this is always very incomplete, so that the sympathectomised foot is protected from reflex vasoconstriction This again is presumably beneficial

TABLE VII—PERCENTAGE INCREASE IN BLOOD-FLOW IN 11 SYMPATHECTOMISED FEET PRODUCED BY BODY HEATING IN PATIENTS WITH OBLITERATIVE AND NON-OBLITERATIVE DISEASE

Obliterative disease		Non-obliterative disease	
Patient	% increase in foot blood-flow on body heating	Patient	% increase in foot blood-flow on body heating
30	31	15	24
61	17	29	44
67	11	36	11
	57		
71	13		
82	51		
99	58		
113	11		

N B—Patient 67 had had a bilateral sympathectomy

20 limbs of patients in the obliterative disease series who reported back for blood-flow measurements had been sympathectomised for an ischæmic skin lesion of the foot which had healed after operation The mean resting blood-flow in these limbs (table VIII) was 3 7 ml per 100 ml foot per minute This was well above the mean flow in the non-sympathectomised feet of the patients as a whole with obliterative disease, and was clearly a major factor in promoting healing 4 of these limbs actually showed some significant return of vasomotor activity on the vasomotor test, but this has not detracted from the sustained good result of operation, as the feet have remained healthy

Conclusion

Blood-flow measurements give objective physiological support for the view that lumbar sympathectomy is a good operation for promoting the healing of existing ischæmic skin lesions and the lasting prevention of further ones

Summary

1 The late effects of lumbar sympathectomy on blood-flow in the lower limb in 61 patients suffering from obliterative vascular disease has been measured For comparison, 18 patients sympathectomised for non-obliterative disease of the lower limbs have also been investigated

2 Lumbar sympathectomy produced a lasting doubling or trebling of blood-flow in the foot, and there was no evidence of this falling off with time during the period of review, one to seven years after operation

3 11–12% of sympathectomised limbs showed partial recovery of sympathetic vasomotor activity when examined between one and seven years after operation But this was always very incomplete

4 The beneficial effect of operation on the healing of ischæmic skin lesions is discussed

TABLE VIII—MEAN RESTING BLOOD-FLOW IN 20 SYMPATHECTOMISED FEET OF OBLITERATIVE-DISEASE PATIENTS OPERATED ON FOR ISCHÆMIC SKIN LESIONS, AND EFFECT OF BODY HEATING

FURTHER EXPERIENCES WITH INTRATHECAL AND SUBDURAL PHENOL

OBSERVATIONS ON TWO FORMS OF PAIN

R. M. Maher
M.D. Lond., B.Sc. Lpool, M.R.C.P.
PHYSICIAN, ROCHDALE HOSPITAL GROUP AND COUNTY BOROUGH OF OLDHAM, PHYSICIAN-IN-CHARGE, PAIN RELIEF CENTRE, MANCHESTER REGIONAL HOSPITAL BOARD

During the investigation and treatment of 164 cases of cancer, it became clear that two types of pain could be distinguished by the effects of intrathecal and subdural injections of phenol given to relieve pain. My previous articles (Maher 1955, 1957) described treatment directed against *continuous* pain, and for the relief of this pain, improved techniques are discussed below. The other type of pain is a more severe and intermittent *incident* pain, arising mainly from direct impact of bony metastases on nerve endings.

The Conduction of Pain

Before considering pain from such internal stimuli, the different nerve elements associated with pain generally will be reviewed.

A and C Fibres

The possibility of a series of nerve impulses travelling along a mixed nerve became apparent after the classical work of Erlanger and Gasser (1927), who, by studying the action-potential of nerve, found different conduction-rates in its components, and this led to a classification into alpha, beta, and gamma waves.

Later, all three waves were grouped under one title—A waves, corresponding to the large A fibres of the nerve, because it was later observed that stronger stimulation revealed other slower waves corresponding to a further set of fibres hitherto unstimulated. Those with the slowest conduction-rates (0·3–1·6 metres per sec.) were found to correspond to the small non-medullated fibres for pain and were called C fibres. The B fibres of medium speed were identified by Bishop and Heinbecker (1930) and correspond to preganglionic neurones connected with the autonomic nervous system.

At present the different nerve-fibre groups may be summarised thus:

(1) Large A fibres, size 1–20μ, conduction-rate 30–100 metres per sec. Conduct alpha, beta, and gamma waves for touch, heat and cold, pain, and motor impulses.

(2) Medium or B fibres, rate 10–20 metres per sec. Preganglionic afferents.

(3) Small C fibres, non-medullated, rate 0·3–1·6 metres per sec. Conduct impulses for pain.

Destruction of A fibres relieves pain but also removes all forms of sensation, with accompanying loss of tone and power. Destruction of small C fibres alone relieves pain, with mild cutaneous analgesia at the most—that is, cutaneous sensation remains intact with no effect on tone or movement (Maher 1957).

There are now known to be two main conducting pathways for pain at the periphery—namely, the swift A and the slow C paths.

The two pain sensations after cutaneous stimulation were first identified by Rosenbach in 1884. This observation was confirmed by Gad and Goldscheider (1892), but they were in error about the nature of the second pain, which was more correctly interpreted by Thunberg (1902).

By 1934 Gasser had shown that the first pain was conducted by A fibres and the second by C fibres. The whole question of the double pain was investigated in man by Lewis and Pochin (1937, 1938) and reviewed later by Lewis (1942). By observing that local asphyxia abolished the first pain and cocaine the second, they confirmed that two pathways were involved.

The further the point of stimulation from the cord, the greater the separation between the two pain sensations. The interval between the first and second pain was 1·9 sec. when the skin of the toe was stimulated and 0·9 sec. when the upper thigh was stimulated. The first pain, conducted by large A fibres, gave rise to reflex muscular movement.

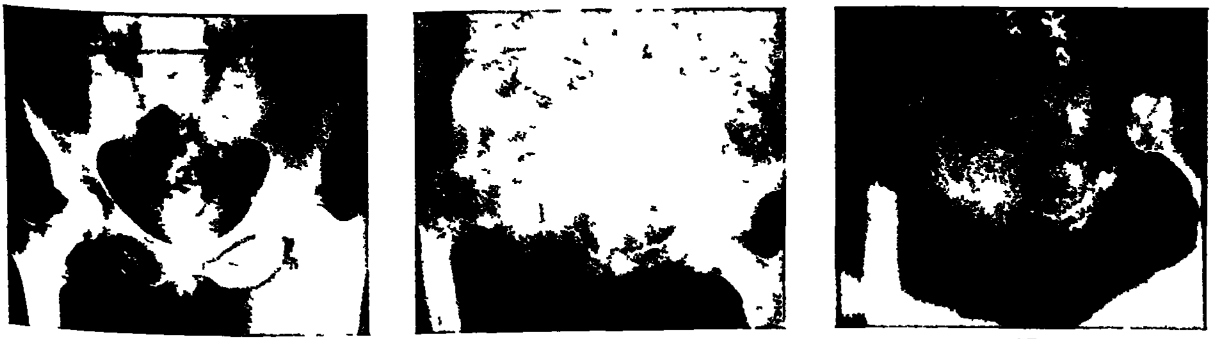
Pochin (1937, 1938) observed that the first or A pain was abolished in tabes. Here application of heat to the foot did not give rise to the first pain and immediate reflex withdrawal, but to delayed and deliberate movement later: only one pain sensation—the second—was experienced.

To summarise these findings, the first pain requires a greater stimulus to evoke it, and it is swiftly conducted, suggesting an emergency pain with accompanying defensive reflexes. The second pain is provoked by lesser stimulation, lasts longer, is slowly conducted, and could be termed a "reminder" pain at the site of injury. So far, however, these results deal largely with pain experiences produced from outside the body. It is of interest to explore how far such findings can be related to pain arising from within.

(c)

Recurrence of Pain after Injection of Phenol

If all *continuous* pain has ceased after injection of phenol, under what conditions can pain return in the area deprived of these afferent impulses? Firstly, regeneration by growing in of other fibres is possible, but in only 1 of my cases, after $3^1/_2$ years' total relief,



(a) (b) (d)

Fig 1.—Case 1 (*a*) invasion of right ischiopubic ramus, (*b*) pathological fracture of femur and further destruction of pelvis, June 18, 1957, (*c*) patient out of bed two days before discharge on June 30, 1957, (*d*) gross general deformity of pelvis but no pain.

has this seemed at all likely Secondly, a further pain pathway may be stimulated This recurrence is usually associated with fracture or vertebral collapse and these pains have been called " incident " pains

Illustrative Cases

The following details are taken from 16 cases chosen as examples

CASE 1 —A woman of 50, with carcinoma of the breast and metastases, underwent radical mastectomy in February, 1956, and later was given androgens and irradiation Pain began ten months later Fig 1a shows invasion of the right ischio-pubic ramus From the right groin and thigh, pain areas had extended until some 18 roots were involved, illustrated on the pain segment diagram (fig 2) Beginning on Jan 28, 1957, intrathecal injections were given, first on the right (1 ml of 1-in-25 phenol in glycerin, containing silver nitrate gr $^1/_{30}$ [0 0022 g]) at D12–L1 interspace Injections of 1 ml of 1-in-20 phenol were then given at L4–5 interspace on both sides and at D12–L1 on the left She became totally free from pain

Six weeks later she was readmitted with sudden extreme pain in the right hip She had heard the cracking of her femur while walking in the garden The limb was fixed between sandbags After a few days all pain ceased spontaneously without further injections Fig 1b shows the fracture accompanied by further pelvic destruction, and fig 1c shows the patient out of bed two days before discharge on June 30, 1957 Complete alleviation continued for six months until she had pain in the neck due to metastasis in the cervical spine

On Dec 4, 1957, subdural injection at C5–6 of 4 ml of 1-in-10 phenol in 'Myodil' gave permanent relief for this site The original dorsolumbar segments continued free of pain, and X-ray examination revealed further destruction of the bony pelvis, which two months later was nearly complete Six weeks later there was gross deformity (fig 1d) but still no pain She died on March 22, 1958, and necropsy revealed total destruction of the bony pelvis and extensive invasion of the lower abdomen

There were clearly two separate pain experiences The initial pain was continuous and spread to involve most of the neurones below the groin on both sides, and it was totally relieved by successive intrathecal injections After two months' complete relief, the severe " incident " pain of fractured femur developed suddenly within the relieved area For this pain no further injection was required, and it subsided completely after a week or so with rest and support by sandbags Total relief continued for a year afterwards and movement of the right leg, though limited by the fracture, was painless

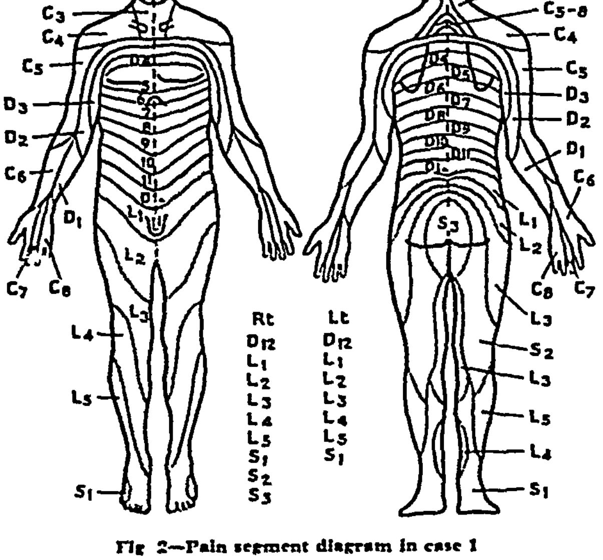


Fig 2—Pain segment diagram in case 1

CASE 2 —A woman of 59, with cancer of the cervix, was treated in 1953 by panhysterectomy and irradiation Pain in the left groin began the following year at the site of a hard mass Subarachnoid 1-in-20 phenol in glycerin at L1 was followed by a series of lumbosacral injections for both sides below D12 All sites must have been covered, because relief continued for eighteen months A severe pain incident was relieved by rest only, and X-ray examination in November, 1955, showed advanced destruction of the bony pelvis with a fracture in the right pubis Two weeks before she died in January, 1956, she was attempting to walk by pushing a chair in front of her

CASE 3 —A woman of 25 with cancer of the right breast and vertebral collapse at D12–L1 After injection of 1-in-20 phenol for pain down both legs, " continuous " pain was eliminated but pain on movement remained After immobilisation in spinal flexion for one month, relief continued for six months until she died

CASES 4 and 5 had traumatic fractures after receiving intrathecal phenol, one for spasticity in disseminated sclerosis and the other for pain due to cancer of the cervix Both had very brief pain, lasting only a few hours

CASE 6 —A woman of 53, with adenocarcinoma of the breast, underwent radical mastectomy in October, 1957 Adrenalectomy in July, 1958, gave no relief and pain became violent After 1 8 ml of 1-in-20 phenol in glycerin from L1 level at 30°, pain subsided, and X-ray examination showed fracture of the left femur Rest and fixation gave complete freedom from pain for eight months before she died

CASE 7 —A woman of 53, with carcinoma of the right breast and spinal metastasis Severe pain in the back began in February, 1957, and X-ray showed collapse of L1 and severe angulation to the left (fig 3a) After irradiation to the spine and testosterone propionate she became pain-free until November, 1957 Intense pain then developed down the front and back of both thighs and extended to the feet Fixation alone was found ineffective Pain became intolerable in February requiring morphine and analgesia constantly On Feb 26, 1958, subarachnoid phenol was given for both sides at one session This was only possible by strapping the patient in the anterior half of a plaster bed after she had had morphine At D11–12 2 ml of 1-in-20 phenol in glycerin was made to flow along the left side intrathecally along a caudal slope of 30°, thus probably covering 9 roots After 20 minutes the patient was rotated in the plaster to lie on the right side and 1 5 ml of phenol 1-in-20 in glycerin was allowed to flow caudally at 30° Some 18 roots must have been influenced below D11 After this extensive injection the patient was supported, without the plaster, in spinal flexion and inclined to the right, to try to get the weight of the collapsed vertebræ off the roots, especially on the left After two weeks she became pain-free and was discharged on March 14 She remained at home in the flexed position for two months, and then began to move without pain In June, when she got up, spinal flexion had become stabilised, altering her balance somewhat, but walking became normal Complete relief lasted for over two years (fig 3b was taken in October, 1958), and then she was immobilised by a fracture of the femur

A patient bedridden with spinal secondaries and intolerable pain was treated in June, 1958, by intrathecal injection, and after eight weeks was able to walk without pain for over a year so far

2 advanced cases had similar treatment and relief, but walking was not possible

2 patients were not relieved by subarachnoid phenol from the continuous pain, and incident pain persisted on movement

Another 2 patients with spinal secondaries and pain in the legs from cancer of the breast are now pain-free and walking, following the same procedure, but 1 had adrenalectomy later

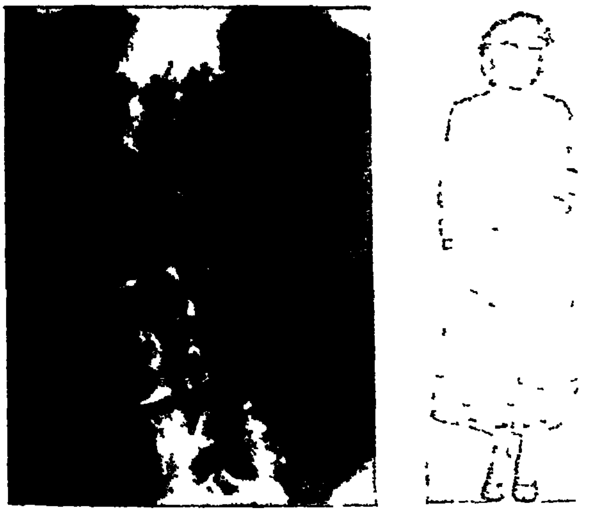

Fig 3—Case 7 (*a*) Angulation of spine in February, 1957, (*b*) patient in October, 1958, nearly a year after first onset of intense pain.

2 patients with cancer of the lung and spinal metastasis were relieved of pain in the arm by subdural injections followed by fixation in plaster

The successful cases demonstrate that "reminder pain" fibres must have been eradicated completely, despite months of continuing cancerous invasion The selection of these fibres by phenol enables the supervening severe "incident pain" to be clearly identified Incident pain is due to direct stimulation of nerve-fibres or nerve-endings during sudden happenings such as fracture or vertebral collapse. Provided continuous pain had been relieved by phenol, absolute rest prevents friction or impact on the nerve and relieves the incident pain. The necessary period of rest after vertebral collapse is two months or more Afterwards, since renewed movement did not provoke pain, processes of repair must have prevented stimulation of the nerve. Moreover, the spine became fixed in the adopted position of flexion Conditions in the spine therefore closely resembled those of Pott's disease undergoing repair In case 1, relief continued for a year after fracture, and the bony pelvis was found to be one soft mass, which could minimise stimulation and incident pain

Continuous pain suggests stimulation of small C fibres, but it may itself increase with movement it can be eliminated by phenol Violent pain, indicating an "incident" or emergency, may be conducted along large A fibres

Transmission of the Two Pains

How far these two pains are related to the two pains of external stimuli (Lewis and Pochin 1937) is hard to say The effects of phenol have, however, thrown some light on this question. The greatest impact of 1-in-20 phenol intrathecally is on pain fibres not included with those for touch, tone, and movement, which are not demonstrably affected Except when silver nitrate was included or too much phenol given no final cutaneous sensory changes were observed When permanent relief ensues despite continuing penetration by growth these fibres must have been destroyed, and a different pain arising later from fracture might be taken to imply conduction along the only alternative pain path known—the A fibre group

Using the timing tests of Lewis and Pochin (1938) with the copper cylinder at 63°C, varying results were obtained in 6 patients who had had intrathecal phenol. Sometimes there were curiously patchy changes in sensation the effects shortly after intrathecal phenol in 2 cases showed one or two small areas with no sensation at all, all pain, swift and slow, had been abolished. All other areas gave a fast response of 0 4–0 6 sec. The second pain was recorded at 1 6 sec. from the ankle (75 cm nerve length) except in the area analgesic to pinprick after injection

The later result in other cases was usually abolition of the second pain where the area was relatively analgesic after injection of silver nitrate or a greater concentration of phenol. In 2 patients relieved without analgesia, the second pain was not abolished, and was recorded in 1 5–1 7 sec. from the ankle.

It seems that all fibres in the roots are affected immediately after phenol injections The sensory effect wanes and after normal doses it is rare for sensory change to persist—an observation which coincides with the findings of Nathan and Scott (1958) In my series the timing tests show that with the smaller doses the second pain of Lewis and Pochin was unaffected But, when greater amounts of phenol or silver nitrate were used, giving permanent relative analgesia, this second pain was abolished, suggesting that the small C fibres were eliminated. In general, however, subjective pain is relieved without inducing objective sensory changes The whole phenol effect seems to be quantitative, with cutaneous C-fibre loss predominating

Non-malignant Conditions

The risk of causing incapacity limited the use of intrathecal phenol in the treatment of non-malignant conditions (Maher 1957, Brown 1958) I often tried first the effect of extradural and trans-sacral injections, but for conditions with an existing disability intrathecal phenol was more clearly indicated It was first used successfully for spasticity with flexor spasms (Maher 1957) and extended afterwards to other kinds of spasticity and parkinsonian rigidity Phenol (1 in 20 in glycerin) was first used in doses up to 1 ml Smaller doses, never exceeding 0 5 ml at one time, have been given for pain with disability from arthritis, spondylitis, and failed disc operations (26 cases) Sensory and root reactions to phenol are much more pronounced in non-malignant states, so it is safer to grade the phenol doses by skin testing as described below 0 3 ml of 1-in-20 phenol once reached the "endpoint" of relative analgesia with retained touch sensation, and no more was injected

Test solutions—As a further guide before injecting lumbosacral sites, successive doses of cinchocaine hydrochloride ('Nupercaine'), gr $^1/_{16}$ (0 004 g), gr $^1/_8$ (0 008 g), and gr $^1/_4$ (0 016 g) in 1 ml. of glycerin, were injected intrathecally to give a temporary effect corresponding to 1-in-20 phenol. This precaution was first used for spasticity in 1956 and has been continued since to give a preview of the result. In 6 cases tested, gr $^1/_{16}$ of cinchocaine seemed to match 1-in-20 phenol, but more results must be studied. The cinchocaine effect took much longer than that of phenol to become manifest.

For a given injection site and slope of the patient, the effect of cinchocaine may enable resistance of the nerve-roots to phenol to be predicted in 2 recent cases no reaction to the test solution corresponded with resistance to phenol. For the treatment of pain, temporary relief from cinchocaine gr $^1/_{16}$ indicated that 1-in-20 phenol would also give relief Relief from cinchocaine gr $^1/_8$ meant that the roots were hard to penetrate and relief less certain.

Certain inferences may be drawn from findings in cancer For instance, abdominal pain from cancer has two main sources (*a*) perineural metastasis, and (*b*) peristaltic pain from partial obstruction (*a*) can be relieved by 1-in-20 phenol, but for (*b*) there was no relief this difference may be due to a different level of entry of fibres into the spinal cord When stronger solutions were injected bowel movements diminished It may be that the colics and the onset of the acute abdomen are incident pains arising from stimulation of large fibres and accompanying reflex rigidity It is well known that tabetic patients may die from unrecognised acute abdominal conditions, because of the absence of pain, and similarly, a patient with cancer, who had had higher concentrations of phenol than usual, had no abdominal symptoms after perforation of a stercoral ulcer

Present Techniques

The procedures now in use include the following methods

The initial areas of pain are mapped on standard charts (fig 2), on which any residual pain areas after injection are also recorded These charts make it possible to place the injections more accurately and fig 2 shows a case in which some 18 roots may need attention Injections are continued until pain is totally abolished five days after injection If pain returns after 3 or 4 root injections, the siting of the injections may be inadequate or more phenol may be needed

Control of Phenol Injection by Sensory Changes

At the dorsolumbar level (intrathecal 1-in-20 phenol in glycerin), sensory effects from an initial 0 3 ml give a good idea of the position of the needle For D12–L1 injections, changes in sensation should then immediately correspond with the segments reached The bevel of the needle should be directed downwards towards the required roots in the lateral lumbar position, with a slight caudal slope After this first dose, paræsthesiæ should soon be felt in the groin or thigh If not, a slight and temporary increase in caudal slope may evoke them If, however, the initial sensory symptoms appear in the sciatic group, particularly the foot or leg, injection should be abandoned, and attempted again a day or so later Sensory symptoms in the foot indicate that the needle is too far over to the unaffected side and that phenol is flowing over the cauda equina The nervous mechanism for micturition may be damaged if phenol covers the lowest part of the cord

The immediate sensory symptoms induced by intrathecal phenol can be matched against the final result The order of events is as follows First, instantaneous relief is common, followed by tingling and paræsthesiæ at the appropriate site There follows diminished sensation to pinprick and scratch, *compared with the opposite side* After further doses, pinprick and scratch sensation may vanish, but light touch is unaffected Later, light touch diminishes compared with the opposite side Finally, light-touch sensation and scratch may cease and the limb become awkward If this is *permanent*, movement of the limb may be impaired

This sensory-gradation method of controlling injections is based on the fact that light touch is conducted by large fibres and, if it is unaffected, the other large fibres for tone and movement are also intact A dose of 1 ml may be insufficient for some patients and too much for others A total of 1 2 ml or more can sometimes be used, but, in 3 instances, 0 5 ml was the maximum possible dose

It is very necessary, therefore, that tests for sensation should be repeated after each 0 3 ml has been injected, and *light touch must not be affected* Sensation in the groin is particularly important during L1 injections

The "endpoint" for stopping the injection is diminution or loss of scratch and pinprick, with light touch intact, and the injection can be continued until this stage is reached

For injection at L4–5 for pain in the lower limb and sacral segments similar tests are carried out, and usually 0 5–0 75 ml is the total required Larger doses may reach the 2nd, 3rd, and 4th sacral units

During the study of 20 cases of disseminated sclerosis by Dr L A Liversedge and myself, fear of damaging the sacral nerves, and so causing urinary dysfunction, led us to adopt covering agents Before injecting phenol in glycerin at L2–3, subarachnoid puncture at L5–S1 was used to introduce either pure myodil or glycerin alone over the sacral roots This prevented urinary dysfunction in 5 out of 6 cases with existing disability of micturition A day or two's temporary incontinence followed injection in these circumstances

Other Intrathecal Injections

For *pain in the rectum* and bottom of the coccyx, such as may follow the abdominoperineal operation, subarachnoid puncture is done at *L5–S1 with the patient vertical, and he then* lies on the side of greatest pain, with the trunk elevated to 20° with the horizontal 0 7 ml of 1-in-20 phenol in glycerin is allowed to flow gently down the lateral dura to the end of the dural sac The patient is then gradually raised to the vertical The phenol must not be allowed to diffuse through *all* the sacral roots because that would cause retention This was the disadvantage of the original vertical-drop method (Maher 1957) After a few seconds, the patient is turned over to the opposite side at 15° elevation

For *upper abdominal and lower thoracic pain* subarachnoid puncture at D9–10 is preferable The patient lies with the pelvis elevated to 20° 0 5 ml of 1-in-20 phenol in glycerin is used as the initial solution *If there is no effect on the lower limbs* 1 5–3 ml of 1-in-15 phenol can be slowly injected Silver nitrate gr $^1/_{100}$ with 1-in-25 phenol is an alternative

Extradural Injections

For *cervical and upper dorsal pain* puncture and injection are performed with the patient sitting upright When cerebrospinal fluid flows, the needle is withdrawn steadily 1 mm at a time, until the flow of C S F nearly ceases *0 5 ml 1-in-20* phenol in glycerin is then used as a trial If tingling is felt in the back below the needle, the phenol is still intrathecal and is flowing downwards If there are no symptoms 1-in-15 phenol can be slowly and carefully injected If air is also injected at the same time the phenol descends slightly and affects the upper dorsal roots, which may be involved in cancer of the lung Recently, this method has produced improvement in 4 out of 8 cases of lung cancer

Trigeminal Pain in Cancer

By using Harris' route over the sigmoid notch of the mandible (Harris 1937) and inverting the head so that the orbit is higher than the mastoid (fig 4), 1–2 ml of 5% aqueous phenol will flow towards the foramen ovale at a needle depth of $1^1/_4$ in The foramen ovale should *not* be penetrated The injection may be repeated if necessary 18 out of 24 cases were relieved Injection of phenol in glycerin is difficult, it was used until recently No sensory changes have been noted

Factors influencing Final Results

Intrathecal phenol is effective for lumbosacral and dorsal sites below D3 relief was complete in 61 out of 81 cases Recently, using the gradation method of injection control, relief was attained in 12 out of 14 cases Above *D3* intrathecal phenol is not used Subdural phenol gives better results for cancer of the lung, originally only 1 in 5 were relieved, but recently 1 out of 8 patients were freed from pain by the new methods

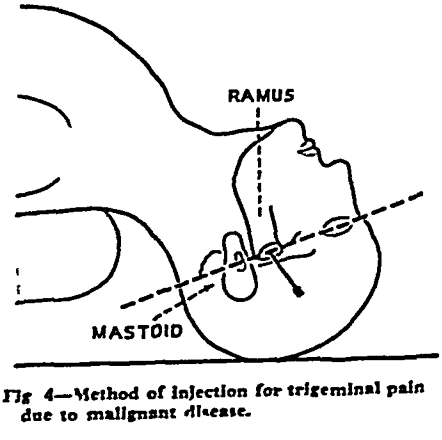

Fig 4—Method of injection for trigeminal pain due to malignant disease.

Originally patients were referred for treatment late in their illness, and complete resistance to phenol often corresponded to growth around the ganglia and roots (the "sheltering" phenomenon) (Maher 1957) Now with earlier treatment a gradual increase in resistance is noted as the disease advances Phenol is very potent with small areas of early pain, and sometimes 0 3 ml of 1-in-20 phenol was the maximum dose permissible Pre-existing root damage by cancer may be responsible for this effect

Glycerin, used for the early injections in 1955, is still the conveyor of choice for all subarachnoid injections Myodil tends to protect the roots and interfere with any later injections that may be needed

1 ml of phenol will cover only three roots at a time In fig 2, 9 or 10 roots on each side need attention at three or four sessions Further injections can be given later Provided relief is progressive, the effect on morale is good If phenol-treated segments do not respond, phenol/silver-nitrate mixture can be used The aim is to continue injections until all pain has, if possible, been relieved

Phenol Mixtures with Silver Nitrate

At lumbosacral sites only, 1-in-25 phenol in glycerin mixed with silver nitrate gr $^{1}/_{100}$ or gr $^{1}/_{80}$ was used when phenol alone was not enough Above lower dorsal level it was considered unsafe (Maher 1957) After the experience of Nathan and Scott (1958), it was tested further at various concentrations for lumbosacral sites

In 21 cases gr $^{1}/_{30}$ (0 0022 g) of silver nitrate per ml of agent gave relief in 15 resistant cases In 6, severe meningeal symptoms followed the injection In 33 cases gr $^{1}/_{100}$ (0 0006 g) of silver nitrate per ml gave relief in 23, with slight meningeal symptoms in 1 In 18 cases gr $^{1}/_{150}$ (0 0004 g) silver nitrate per ml gave relief in 13 with no accompanying meningeal symptoms There were no fatalities among patients treated with silver nitrate With the greater concentration, gr $^{1}/_{30}$ (0 0022 g) meningeal symptoms were alarming in 2 patients, and arose within a few minutes of injection pain began at the site and spread headwards, requiring morphine

The most effective concentration was gr $^{1}/_{100}$ (0 0006 g) per ml of 1-in-25 phenol in glycerin As an additional precaution 0 5 ml was sometimes injected as a trial After 20 minutes, in the absence of symptoms, the remaining 0 5 ml. was added Morphine (gr $^{1}/_{6}$) half an hour before injection is of value

It is important to keep the patient lying still in the injection position for an hour afterwards this localises the agent to the required roots Attacks of pain decrease with time and die out after a week.

Of the 25 lumbosacral cases unrelieved by phenol alone, 15 were free from pain after phenol and silver nitrate (Maher 1957) Silver nitrate has become less necessary now that cases are referred earlier Moreover, phenol alone is made more effective by the method of gradation described above There is no doubt, however, that the phenol/silver-nitrate mixture is the most powerful agent for relief, and gr $^{1}/_{100}$ per ml was found to be safe

Preparation of Phenol/Silver-nitrate

To prepare a solution containing silver nitrate gr $^{1}/_{100}$ (0 0006 g) per ml of 1-in-25 phenol in glycerin (usual dose 1 ml), 24 ml of sterilised glycerin is added to a 30 ml amber 'Clinibrittic' bottle, washed and sterilised by dry heat at 150°C for one hour

Solution 1 —1 g of phenol crystals are added to this 24 ml of sterile glycerin A sterile rubber cap is fitted

Solution 2 —Ampoules of silver nitrate containing gr 5 (0 3 g) in 6 ml of water for injection are prepared and autoclaved

Take 0·3 ml of solution 2 and add to solution 1 Add 0 7 ml further of water for injection, to bring the total volume to 25 ml

Conclusion

Specialists in cancer and orthopædic surgery have long noted that immobilisation often brings relief of pain in malignant disease I have attempted to explain this in terms of the type of pain transmitted by different fibres, and to show how the removal of more slowly conducted pain can assist in relief of the swift emergency pain With pain abolished, patients seemed to live longer, and repair in the spine was sometimes sufficient for some months' walking Perhaps irradiation and androgens were given more time to act Measures such as irradiation, adrenalectomy, and androgens have prolonged life, but the first essential is relief of pain, and here injection methods may aid surgical procedures

I am deeply indebted to Sir Geoffrey Jefferson and Mr R T Johnson for their encouragement and advice My thanks are also due to the Manchester Regional Hospital Board for their grant and for the establishment of a Pain Relief Centre I should like to thank also Dr and Mrs J Starkie, Mr and Mrs J Edmonds, and Mrs E Ashworth I acknowledge too the great assistance I received from Dr J Shrigley in the study of the pathological findings

INTERMITTENT POSITIVE-PRESSURE RESPIRATION AND THERAPEUTIC BRONCHIAL LAVAGE IN INTRACTABLE STATUS ASTHMATICUS

BRYAN BROOM *
M B Lond.
FORMERLY MEDICAL REGISTRAR, SALISBURY GENERAL INFIRMARY

ONLY in recent years has it been realised that death from uncomplicated bronchial asthma is not rare (Earle 1953)

Probably there are about 400,000 asthmatics in the United Kingdom in any one year (Stocks 1949) The reports of the Registrars General infer that each year about 3000 people die directly owing to bronchial asthma (Robertson and Sinclair 1954) Westlund and Hougen (1956) gave a mortality of 12 5% from "pure" asthma in a follow-up survey of the 327 patients seen at the Ulleval Hospital, Oslo, between 1917 and 1936, Williams and Williams (1949) followed up 64 cases of bronchial asthma for from seven to twelve years and found that 17 2% had died from asthma

While opinions differ as to the relative importance of the several factors operating in asthmatic bronchial occlusion, all workers emphasise the predominant role of viscid mucus as the final cause of asphyxia In a review of reports published between 1922 and 1951 (Earle 1953) only 6 of the 90 cases cited did not show "the bronchial tree plugged with sticky mucus"

As Houston et al (1953) point out "There is no doubt that the majority of patients diagnosed clinically as being in status asthmaticus recover, and presumably in these patients there is only partial bronchial plugging with added bronchial spasm which in time becomes amenable to treatment" Recent accounts include necropsy reports of at least 6 patients who died in status asthmaticus while on cortisone, and all reports refer to typical bronchial mucus plugging (Davies and Williams 1955, Houston et al 1953, Robertson and Sinclair 1954, Savidge and Brockbank 1954)

---

* Present address Atkinson Morley's Hospital, London, S W 20

Since February, 1959, there have been 3 consecutive deaths from uncomplicated status asthmaticus in Salisbury General Infirmary, despite energetic orthodox treatment which included steroid therapy in each case In all 3 cases necropsy revealed thick bronchial mucus plugging The following two cases are reported to indicate what seems to be a successful line of treatment in the otherwise hopeless case of status asthmaticus

Case-records

Case 1 —A woman, aged 40, had had bronchial asthma for ten years Her general practitioner stated that she was "a nervous, tense, and timid person who fears to have another child and is afraid of being shut in" The total duration of her attack was five days, of which the last two days had been spent in hospital

Aug 27, 1959 noon —Admitted with severe dyspnœa, not cyanosed, chest expansion poor, much audible wheeze, percussion note resonant, pulse-rate 140 per minute, blood-pressure (B P) 150/100 *mm* Hg The *following treatment* was started intramuscular chlorpromazine 100 mg , intramuscular promethazine 100 mg , intramuscular pethidine 50 mg six-hourly, oral prednisone 15 mg six-hourly, and 1 megaunit soluble penicillin eight-hourly

3 p m —Well sedated

7 30 p m —Much deterioration over past twenty minutes cyanosed and grey, wheezing stridently, pulse-rate 160, B P 90/70 0 5 g thiopentone and 100 mg succinylcholine given intravenously and endotracheal intubation performed with cuffed no 10 Magill tube Light ether anæsthesia maintained with 2 litres oxygen per minute, from Boyle's machine

8 p m —Intravenous drip set up with 100 mg hydrocortisone and 500 mg succinylcholine in 500 ml physiological saline solution Positive-pressure respiration maintained at rate of about 10 per minute Colour pink and wheeze apparently less, B P 100/70

10 30 p m —No expansion of chest on positive pressure, B P 80/50 Tube removed and found to be blocked with thick mucus Another Magill tube inserted and many plugs of mucus aspirated, with Tiemann's coudé catheter attached to oxygen sucker Chest movements satisfactory after this procedure

Aug 28 12 30 a m —Wheeze worse, pulse-rate 140, B P 90/60

1 a m —No chest expansion on positive pressure Trypsin (calcium salt) 50 mg in 10 ml physiological saline flushed down endotracheal tube, after attempted aspiration unsuccessful Much mucus aspirated one minute later Chest movements satisfactory

4 a m —No chest expansion on positive pressure Trypsin lavage repeated with similar effect

9 a.m —General condition much improved and wheeze apparently decreasing, chest expansion good, B P maintained at 140/90

Noon —Progress maintained, wheeze almost gone

5 p.m —Intravenous drip discontinued and spontaneous respiration allowed to recommence

6 p.m —Anæsthesia discontinued and endotracheal tube removed No wheeze apparent.

7 p.m —The patient took a light supper

The Magill tube had been deflated every four hours Two litres physiological saline, 400 mg hydrocortisone, and 2000 mg succinylcholine had been given over twenty-four hours

Subsequent progress was uneventful, chest radiograph was normal The patient was discharged on *Sept 16*

Case 2.—This patient, a man aged 64, had "never had a day's illness" until three years ago when he contracted influenza, a "nervous breakdown" followed, which had not been improved by his daughter narrowly escaping a second divorce in the U S A He had noticed that the asthma came on when he got "stirred up" The total duration of his attack was four days, of which the last two days had been spent in hospital

Oct 2, 1959 11 30 p m —On admission the patient was anxious, dyspnœic, not cyanosed, poor chest expansion, percussion note resonant, severe wheeze, pulse-rate 100, B P 120/80 Aminophylline 0 75 g administered intravenously with good effect, chlorpromazine and promethazine 100 mg given intramuscularly Penicillin 1 megaunit eight-hourly started

Oct 3 1 45 a m —General condition deteriorated, restless and cyanosed, B P 100/70 Prednisolone 50 mg given intravenously with good effect

3 45 a m —General condition somewhat improved, no cyanosis but restlessness persisted Chlorpromazine and promethazine 100 mg given intramuscularly

5 45 a m —Improvement maintained, no cyanosis, B.P 120/80 Prednisolone 25 mg given intravenously

8 a.m —Patient collapsed, B P 80/60 Thiopentone 0 5 g and succinylcholine 100 mg given intravenously, and cuffed endotracheal Magill tube (no 10) inserted Intravenous drip set up with 500 ml physiological saline solution, 750 mg succinylcholine, and 25 mg prednisolone Continuous anæsthesia started with 2 litres oxygen and 4 litres nitrous oxide per minute, from Boyle's machine Positive-pressure respiration maintained at rate of about 10 per minute

8 20 a m —General condition still poor, much mucus aspirated with Tiemann's coudé catheter connected to oxygen sucker Chest movement improving, pulse-rate 140, B P 100/70 Cyanosis relieved by aspiration

9 30 a m —No cyanosis, B P 130/80

10 40 a m —No chest expansion on positive pressure, cyanosis, B P 80/60 Trypsin (calcium salt) 50 mg in 10 ml physiological saline solution flushed down endotracheal tube, and after one minute much mucus aspirated It was very difficult to get the mucus out of the Tiemann's catheter into the sucker bottle Cyanosis relieved by aspiration and chest movement *satisfactory*

10 50 a m —B P 150/100

12 15 p m —Considerable resistance to inflation, much thick mucus aspirated

2 30 p m —Condition satisfactory, no further *cyanosis* Respirations maintained at about 10 per minute

5 50 p m —Cyanosis and cessation of chest movement. Trypsin lavage repeated as above with aspiration of copious mucus, relief of cyanosis, and return of chest expansion

9 15 p m —Aspiration of much mucus

10 30 p m —Succinylcholine discontinued, but prednisolone maintained

Oct 4 12 5 a m —Wheeze very slight, chest expansion excellent

12 30 a m —Suction of much mucus and also gastric contents from oronasopharynx Spontaneous respiration of good amplitude and about 15 per minute B P 130/80

1 a m —Anæsthesia discontinued and oxygen only given

1 30 a m —Vomiting of dark brown juice, stomach aspirated with œsophageal tube and 500 ml fluid removed Endotracheal tube removed

2 10 a m —Patient regained consciousness

2 30 a m —Patient responding to command to cough with great difficulty but with good effect *Pronounced* cyanosis and wheeze attended these efforts

3 a.m —No cyanosis or wheeze Respiration-rate *11* per minute

The Magill tube had been deflated every four hours Between 11 P M on Oct 2 and 2 10 A M on Oct 4, 3 litres of physiological saline solution, 3500 mg succinylcholine, and 135 mg prednisolone were given Subsequent progress in hospital was uneventful, the patient remained apyrexial, the chest radiograph was normal, and sputum culture was negative The patient was discharged on Oct 13

Discussion

The prognosis in status asthmaticus is difficult to assess, but the manifestations and consequences of gross respiratory obstruction cannot long continue unchecked Bronchial occlusion in asthma is initially reversible by bronchodilator therapy, but when death occurs in this disease it is chiefly due to mucus obstruction Orthodox treatment usually ends the acute attack of status asthmaticus, but when such treatment is ineffective the relief of respiratory obstruction may become urgent As asthmatic respiratory obstruction increases, the therapeutic problem becomes one of ventilation in general rather than expiration in particular In the moribund patient the potential hazards of assisted respiration are less immediate than the actual risks of unrelieved anoxia Both "air-trapping" and "airway collapse" can occur with mechanically assisted respiration and may lead to respiratory and circulatory failure (*Lancet* 1959), but that neither is inevitable, over a period of twenty hours, has been shown in this paper Aerosol therapy and bronchoscopic suction are of proven value in status asthmaticus, but they are not always effective (Savidge and Brockbank 1954, Robertson and Sinclair 1954) In the later stages of status asthmaticus, aspiration of mucus involves reaching the main bronchi, and, when the conscious efforts of the patient are insufficient adequately to inspire, expire, or expectorate, anæsthesia is necessary In the extreme case of status asthmaticus, continuous counteraction of the twin hazards of mucus accumulation and ventilatory insufficiency may be necessary (Hugh-Jones 1958)

Summary

3 consecutive deaths from uncomplicated status asthmaticus, despite intensive orthodox measures which included steroid therapy, prompted a search for a more satisfactory treatment

2 patients in status asthmaticus, moribund despite steroids, with chest fixation, cyanosis, and systolic hypotension, were successfully treated by continuous intermittent positive-pressure respiration under anæsthesia, using a Boyle's machine

Regular aspiration was practised, using a Tiemann's coude catheter connected to an oxygen sucker In both patients endobronchial lavage with trypsin enabled aspiration, previously ineffective, to be satisfactorily performed The rapidity with which the mucus was subsequently aspirated suggests that the effect of trypsin was not due to its digestive action

This method seems worthy of further trial in otherwise intractable status asthmaticus

I should like to thank Dr E M Collings and Dr S M Gorringe and many nurses of the Salisbury General Infirmary for their help, and Dr J H Gubbin and Dr R. G M Longridge, under whose care these patients were admitted, for their encouragement

FŒTAL MORTALITY IN ESSENTIAL HYPERTENSION

J M GATE
F R C S E , M R C O G
SENIOR REGISTRAR, JESSOP HOSPITAL FOR WOMEN, SHEFFIELD

OPINIONS differ on the highest level of blood-pressure that can be regarded as normal during the early weeks of pregnancy The commonly accepted figures of 140 mm Hg systolic and 90 mm diastolic have been disputed, notably by Browne (1951) whose standard is 120/80 mm About 1% of women have a blood-pressure of 140/90 mm or over during the early weeks

It is generally believed that hypertension is associated with an increased fœtal mortality Some of the stillbirths are due to premature separation of the placenta, while others have been attributed to placental insufficiency (Browne and Veall 1953, Walker and Turnbull 1953, MacKay 1957, Paine 1957, Russell et al 1957) Browne and Dodds (1942) found that only 32% of patients who began pregnancy with blood-pressures of 150/100 or over gave birth to living children.

After observing several patients who started with blood-pressures far in excess of this, and being surprised to find that the outcome was usually satisfactory, I decided to reappraise the fœtal prognosis in the light of present-day management

Selection and Care of Patients

The series comprised 73 patients in whom the blood-pressure was 150/100 or over before the twentieth week of pregnancy

It was not very easy to find cases which satisfied these criteria, since large numbers of hypertensive patients were not seen until after the twentieth week.

The series was drawn from the patients booked for delivery in the Nottingham Hospital for Women during the three years 1955–58, and in Saint Mary's Hospital, Manchester, during the preceding three years A blood-pressure level of 150/100 was taken as the standard, so that the series could be compared with that of Browne and Dodds No case was included if there was any reason to suspect that the initial reading was fallacious or that the hypertension was transient Often the blood-pressure was very much higher than 150/100

2 of the patients had chronic nephritis and have been excluded

The first line of treatment was insistence on long periods of rest in bed, and usually this involved admission to hospital and sedation with phenobarbitone Antihypertensive drugs, such as mecamylamine or pentolinium, were prescribed in a few severe cases

Induction of labour before term was favoured, and pregnancy was never allowed to progress beyond the expected date of delivery Artificial rupture of the membranes was performed in 26 cases (37%) and cæsarean section in 15 (21%), the indications being

Severe pre-eclampsia	6	Diabetes mellitus	1
Severe hypertension	3	Previous cæsarean section (tender scar)	1
Elderly primigravidæ	2	Prolonged labour	1
Contracted pelvis	1		

Results

1 pregnancy was terminated at twenty weeks because the blood-pressure was 230/150, and because there were retinal and renal changes There were 4 stillbirths and 1 neonatal death The total fœtal loss was therefore 6 (8%)

The average weight of the infants, including the stillbirths, was 6 lb. 10 oz. All the infants which were lost weighed less than 5 lb.

30 patients (42%) developed œdema or albuminuria or both. The neonatal death, and 3 out of the 4 stillbirths, were in this group. There was only 1 case of accidental hæmorrhage and this accounted for 1 stillbirth. There were no cases of eclampsia or cerebral hæmorrhage and no maternal deaths.

Comment

3 out of the 4 stillbirths and the 1 neonatal death were in patients who developed albuminuria or œdema or both—and this at a stage of pregnancy (before thirty-three weeks) when there was reluctance to interfere because of the immaturity of the fœtus. The prevention of this complication is therefore of the first importance.

It may be of value to compare the results of Browne and Dodds, published in 1942, with those of the present series, and to consider the possible reasons for the improved prognosis. Of their 239 patients with hypertension in pregnancy, 25 had a blood-pressure of 150/100 or over before the twentieth week. In these 25 cases, only 8 infants survived (32%). No woman with an initial systolic pressure of 180 mm. or over bore a live child.

In the present series of 71 patients in whom the blood-pressure before the twentieth week was 150/100 or over, 65 infants survived (92%). In 15 cases the initial systolic pressure was 180 mm. or over and in 12 of these a live child was born.

It seems clear that with modern obstetric care a better fœtal prognosis can now be given in these hypertensive cases. The work of Browne and Dodds, by drawing attention to the importance of hypertension and proposing principles for its management, was probably the starting-point of a steady improvement. Emphasis was placed on mental and physical rest, induction of labour before term, and cæsarean section in selected cases.

The wider application of these three principles—particularly the more frequent use of cæsarean section—was probably the main reason for the good results in our series. Progress in the management of prematurity has also contributed to the improvement.

Summary

A series of 71 patients in whom the blood-pressure was 150/100 mm. Hg or over in early pregnancy is analysed. The fœtal mortality is much lower than in a similar series published in 1942, and the difference is largely attributable to better obstetric care.

I am indebted to the consultants of Saint Mary's Hospital, Manchester, and the Nottingham Hospital for Women, for permission to publish these observations, and to Prof. C. S. Russell for advice in writing the paper.

Preliminary Communication

N-TERMINAL-AMINOACID PATTERN IN NORMAL AND PATHOLOGICAL HUMAN SERUM

THE quantitative determination of N-terminal aminoacids of some serum proteins has already been described.[1] The results prompted us to study the N-terminal-aminoacid pattern of human serum proteins. We here report preliminary data concerning the N-terminal-aminoacid pattern of normal serum compared with that from patients with dysproteinæmia.

MATERIALS AND METHODS

Serum was taken for investigation from nine normal subjects, four patients with macroglobulinæmia Waldenström, four myeloma patients (two of whom had cryoglobulins), and two patients with disseminated lupus erythematosus. The clinical findings in all cases were typical, and the diagnoses were all made by J. W.

The N-terminal analyses were usually performed on 1 or 2 ml. of serum previously dialysed against 0·05 *M* phosphate buffer (pH 8·0) according to a recently described modification of the Edman phenyl-thiohydantoin method.[1] [2]

Paper electrophoresis was performed by the method of Laurell et al.[3] Protein content was determined by a biuret method and by a micro-Kjeldahl procedure.

RESULTS

Table I shows the N-terminal-aminoacid pattern of the serum proteins from nine normal subjects. The following N-terminal aminoacids were consistently demonstrated: alanine, aspartic acid, glutamic acid, glycine, leucine (or isoleucine), serine, and valine. Using this method, leucine and isoleucine cannot be distinguished, and arginine, histidine, and cysteine (or cystine) cannot be determined.

The quantitative N-terminal composition of the serum was similar in all the normal subjects. The total amount of N-terminals varied between 8·04 and 9·44 millimols per 100 g. protein nitrogen. Aspartic acid predominated, comprising about 67% of the total N-terminal aminoacids

TABLE I—THE N-TERMINAL-AMINOACID PATTERN IN NORMAL HUMAN SERUM
(millimols per 100 g. protein nitrogen)

Valine	0·53 (5·8%)	0·21 (4·0%)	0·13 (2·3%)	0·60 (6·8%)	0·29 (6·5%)	0·44 (5·9%)	0·50 (6·1%)	0·11 (2·0%)	0·48 (7·4%)		0·49 (5·7%)
Sum	8·90	5·21	5·70	8·84	4·44	7·51	8·25	5·58	6·52	8·27	8·55

Table II shows the corresponding N-terminal aminoacid patterns from the pathological serum specimens These N-terminal patterns differ significantly from those of the normals Thus, only the serum from case 1 had a high content of N-alanine. In all the cases studied N-aspartic acid was more or less reduced N-glutamic acid showed the most variable values in cases 1, 2, 7, and 10 it was increased, in cases 3 5, 6, and 8 it was decreased, and in cases 4 and 9 it was moderately increased. N-glycine could not be detected in four serum specimens (cases 1, 2, 3, and 9), and N-leucine (or isoleucine) was not detected in case 3 but was increased in case 10 The N-serine content was markedly high only in cases 5 and 7 N-valine was within or near normal values in all except case 10, where it was absent The total amount of N-terminal aminoacids was appreciably reduced in cases 2, 3, 5, 8, and 9

TABLE III—THE PROTEIN DISTRIBUTION OF PATHOLOGICAL SERA AS DETERMINED BY PAPER ELECTROPHORESIS
(g per 100 ml serum)

Case no.	Total protein	Albumin	α_1	α_2	β_1	β_2	γ
1	7·80	2·34	0·35	0·56	0·33	0·27	3·92
2	13·50	3·54	0·32	0·47	0·30	0·18	8·69
3	8·30	2·24	0·27	0·34	0·25	0·20	5·01
4	8·64	4·58	0·35	0·60	0·55	0·19	2·37
5	12·10	2·32	0·50	0·61	0·59	0·31	7·77
6	11·50	3·27	0·35	0·58	0·35	0·26	6·69
7	6·66	2·50	0·42	0·66	0·40	0·30	2·38
8	10·62	1·63	0·26	0·40	0·37	0·29	7·67
9	6·70	2·29	0·29	0·53	0·39	0·55	2·66
10	6·00	2·05	0·66	0·96	0·43	0·34	1·57
Normal range	7·64– 6·60	4·89– 4·17	0·41– 0·27	0·63– 0·43	0·61– 0·39	0·44– 0·26	1·08– 0·65

The paper electrophoreses of the pathological serum specimens (table III) showed various degrees of hypergammaglobulinæmia combined with striking hypoalbuminæmia, except for case 4, which had a normal albumin value.

DISCUSSION

Most previous investigations have been concerned with determining the N-terminal aminoacids of a single serum-protein or fraction (see Eriksson and Sjöquist[1]) Human albumin has N-terminal aspartic acid. Human γ-globulin contains N-aspartic acid, N-glutamic acid, and a small amount of N-serine N-aspartic acid and N-glutamic acid, as well as N-serine and N-threonine, have been identified in different lipoprotein fractions[4] As to other serum proteins, little information is available. Transferrin has valine as an N-terminal aminoacid.[5]

Preliminary experiments in this laboratory on an α-globulin fraction (obtained by chromatography on D.E.A.E.-cellulose) have shown that it contains several N-terminal aminoacids (alanine, aspartic acid, glutamic acid, glycine, leucine or isoleucine, and serine) The N-terminal-aminoacid patterns of whole normal serum reported here (table I) agree well with the above findings on individual serum proteins

The diagnostic value of the N-terminal-aminoacid pattern cannot yet be evaluated as only few cases have been examined, and even patients with the same clinical diagnosis had various N-terminal aminoacids It should be noted that sera with almost identical electrophoretic patterns may have strikingly divergent N-terminal aminoacid patterns, and therefore each serum specimen must contain proteins of different chemical structure. The low content of N-aspartic acid in some cases may be explained by the hypoalbuminæmia. This study, however, was not concerned with defining which serum-protein fraction contained the measured N-terminal aminoacid, although this is being investigated. Studies on several abnormal protein fractions from patients with dysproteinæmia have recently been published by Putnam.[6]

This investigation was supported by grants from the Swedish Medical Research Council and from the Medical Faculty of the University of Lund.

" The great challenge at the older ages is how to keep a person fit until he dies functioning as a dynamic unit in the population and contributing to society so that he can maintain his sense of value and dignity It is quite possible that much of chronic disease could be eliminated if physicians knew how to recognise various levels of wellness If, as seems certain, in the lower levels of wellness exist the precursors of future illness, it becomes increasingly important that we be able to recognise the levels of wellness What is top-level wellness? How can one recognize the persons possessing it at the various ages? Can therapy be designed to raise the individual's level of wellness?"—HALBERT L. DUNN, M.D *Journal of the National Medical Association*, 1957, 49, 225

Medical Societies

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE 80th annual congress of the society was held in London on March 31 to April 2, under the presidency of Mr R C DAVENPORT Some of the contributions are summarised below

The Visually Defective Infant

Mr F W LAW discussed the question of whether an infant can see or not, it was usually hard to examine the infant's fundus fully, unless a general anæsthetic was given, and even then it was not possible to be dogmatic about sight unless there was a definite and gross fundus lesion There is also the question of associated mental defect, which may mask the signs of sight in an infant If an infant without sight is brought up in a normal family atmosphere, among normal-sighted companions, the ordinary landmarks of infant progress are reached at the usual time A long-term survey and follow-up has shown that of all the patients seen in one surgeon's outpatient clinic at Moorfields Eye Hospital in City Road in a year, only about 1 child is proved to be blind from birth

Dr RONALD MAC KEITH emphasised that the sensory capacity in an infant was judged largely by what an infant did, and behaviour might be affected and blindness mimicked by any weak link in the chain—sensation, perception, thinking and feeling, motor activity Examination of the degree of partial blindness in infants might be complicated by associated intellectual handicap Of older blind children 25% were ineducable, and perhaps another 25% were educationally subnormal The doll's-eye phenomenon, manifest in the first week of life, is demonstrated by holding up an infant and gently turning it round one way, when the eyes will turn away from the direction of motion In later weeks the eyes turn towards the direction of motion If an older child has the early eye sign, then this may be regarded as a sign of poor vision

The emotional disturbance shown by parents of blind children was preventable if proper steps were taken from the first suspicion of blindness There is then the chance of the child developing a good personality by growing in a warm family atmosphere It is important for a baby to be able to keep in touch with its parent visually and aurally, and if there is visual defect then the aural route is more important and the mother must talk and make noises for the infant to know of her presence

Management of Hormonal Exophthalmos

Dr JOHN LISTER recalled that the classical triad of thyrotoxicosis, goitre, and exophthalmos gave an inadequate picture of the very varied symptomatology of this condition—a complexity to which the great number of possible labels bore witness, his own preference being for " hyperophthalmopathic Graves' disease " And this complexity seemed no nearer resolution while the precise ætiology and pathological physiology remained obscure and its treatment correspondingly unsatisfactory In the management of such cases of hormonal exophthalmos the degree of thyroid function should first be regulated, if it was excessive, antithyroid therapy should be given, but this had the risk of enhancing the exophthalmos, so that reversible measures (antithyroid drugs) were preferable to an irrevocable thyroidectomy when the danger signs of lid swelling, chemosis, or ophthalmoplegia were in any way apparent In euthyroid cases, the anterior pituitary could be depressed by thyroid hormones, œstrogens or steroids, or by irradiation of the pituitary In the hypothyroid cases, thyroid extract should always be given Where intra-orbital tension became dangerously high, diuretics could be given, but these had been of little benefit, and surgical decompression might be necessary

Mr H B STALLARD discussed the surgical measures that might be required to relieve a more severe exophthalmos, and emphasised the importance of a timely tarsorrhaphy in order to protect the cornea, aided if necessary by an orbital fasciotomy and lateral canthal ligament division Where a tarsorrhaphy was impossible or had failed, a large hood-shaped conjunctival flap might yet protect the cornea Orbital decompression was necessary when the optic nerve became too stretched or showed papillœdema—either by orbital fasciotomy and excision of herniating œdematous fat or by a lateral orbitotomy

Mr MURRAY FALCONER emphasised that this disease was usually self-limiting so that a natural remission had often given spurious credit to the various forms of therapy When corneal ulceration was imminent, he preferred a Naffziger decompression, and even if the exophthalmos progressed postoperatively, the orbital contents could then be more easily displaced backwards so that a tarsorrhaphy had the greater chances of success Occasionally these patients died from myocardial infarction, which seemed to have some relation, as yet unexplained, to the hormonal exophthalmos

Mr T KEITH LYLE discussed the surgical treatment of the diplopia which may accrue He first recalled how easily such monocular cases were misdiagnosed, 3 out of his 32 patients had been labelled intra-orbital tumour, 2 suffering a surgical exploration, before a correct diagnosis was reached An operation on the extraocular muscles to correct the secondary squint should be deferred until the condition was static In his cases an average of four years had elapsed before operation The actual squint operations followed the usual pattern, but it was possible to operate on the contralateral antagonist or synergist only if the limitation of movement was mild, otherwise the muscles of the more ophthalmoplegic eye would have to be resected or recessed, and it was most important to avoid any residual limitation in adduction or depression Mr Lyle also described a number of his cases showing a very inconstant visual field loss, presumably due to pressure on or œdematous infiltration of the optic nerve, and sometimes associated with the papillœdema A spontaneous recovery followed

Some Other Subjects

Discussing the advantages and disadvantages of the corneal microlens in comparison to the moulded contact lens, Mr H TREISSMAN said that the new problems presented by the microlens were, if anything, greater than the difficulties normally experienced with the moulded contact lens

Dr C R S JACKSON considered the familiar complaint of asthenopia or " eye-strain " He assessed its age-distribution and the problems of diagnosis, with particular stress on the misuse of spectacles for fine close work

Miss AUDREY MITCHELL discussed the purposeful use of colour, starting with its historical use and symbolic value, its availability and recent technical achievements She described the functional use of colour in various institutions and environments

Dr H O LITTLE said that the treatment of dendritic corneal ulcers required the frequent intravenous injection of vitamins, which had become deficient because of poor assimilation following psychological stress

Dr PAUL WEINSTEIN had noted how anisokoria often followed the dark-room test, which seemed to show that the optico-vegetative and the photo-vasopressor reflexes had importance in the pathogenesis of glaucoma

Mr E S PERKINS discussed those cases of open-angle glaucoma in the younger age-groups, which showed heavy pigment deposits on the trabeculæ, possibly thus obstructing the outflow

Prof B ROSENGREN described an instrument he had devised for indenting the sclera by a silver sphere, in order to bring choroid and retina into apposition during the surgical treatment of retinal detachment

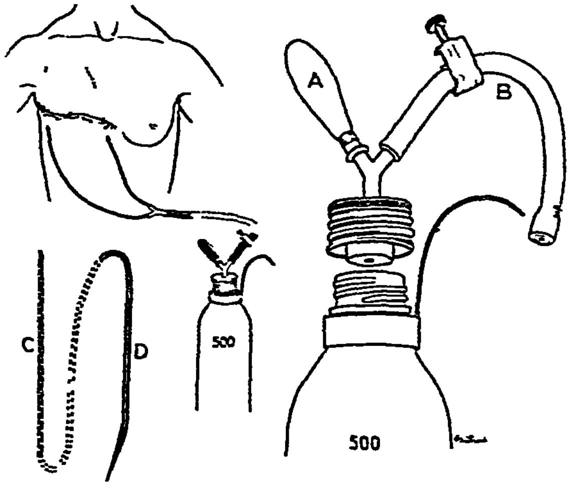
Dr I ISAKSSON discussed congenital blepharoptosis in the light of his anatomical dissections and electromyographic studies, which suggested that there were degenerative changes of the type seen in primary muscular dystrophy

New Inventions

A SIMPLE SUCTION BOTTLE

Obliteration of the dead space in surgery by means of negative pressure has become accepted practice. The methods of applying this negative pressure often have the disadvantages of expense, immobility, and complexity Redon [1] described a method of providing continuous negative pressure by means of a suction bottle, previously exhausted on a powerful electric or Sprengel water pump This has the advantages of being portable, silent, cheap, and easily sterilised. I have been using a simplified version of this bottle which has proved very effective.

The apparatus consists of a National Blood-transfusion bottle sealed with a rubber bung through which passes a plastic Y tube (see figure) To one limb of the Y tube is fixed a rubber teat (A) of the kind which is used on a medicine dropper To the other limb is attached a length of pressure-tubing (B), which carries a screw clip When negative pressure is applied to the bottle, the rubber teat will collapse, when the pressure within the bottle approaches that of the atmosphere, the elasticity of the rubber will cause the teat to re-expand. The critical pressure is 5 cm. Hg The teat therefore acts as a simple indicator of negative pressure within the bottle.



Method of Use

Airtight closure of the skin is effected with sutures or clips and 'Nobecutane' Small-bore drainage tubes (no 4 polyethylene 2 mm. internal diameter 1 mm. wall) are brought out at a separate site. The end of the drainage tube placed within the tissues has a series of lateral holes (C) after the manner of a Carrel-Dakin tube. The tubes are carried through the skin on a carpet bodkin of the same external diameter (D) The blunt end of the bodkin is ground to the same diameter as the inside of the tube and has a series of serrations so that the polyethylene tube once fixed on the end does not easily become displaced. This method of perforation of the skin is simple and assures that the hole exactly fits the diameter of the tube. The polyethylene tube is cut off from the bodkin and pushed into the end of the pressure-tubing issuing from the suction bottle, and the screw clip is released. Sterilised bottles are evacuated to 60 cm Hg through side-arm B before use, and can be stored in this condition for a week or more. Suction will normally be maintained until seepage from the wound has ceased, this in practice will be in 48 to 72 hours When the teat (A) re-expands, demonstrating no negative pressure in the bottle, the bottle should be changed. More than one drainage tube can be connected, by means of a Y tube, to a single bottle, as in the figure

I have found this method effective in closing the dead space in all situations where large areas of skin are raised, or where large tumours are removed. It is of particular use in thyroidectomies, radical mastectomies, parotidectomies, block dissection of the groin and neck, and amputations

The prototype was manufactured for me by A L Hawkins & Co Ltd., 15, New Cavendish Street, London, W 1

Middlesex Hospital,

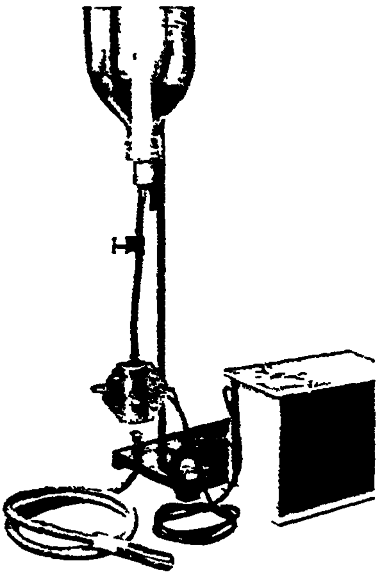
M.A., M.B Cantab, F.R.C.S

A TRANSISTORISED DRIP INDICATOR

The increasing use of drip therapy for intravenous, subcutaneous, and intragastric purposes, leads to a greater strain on the nurses responsible for checking each drip chamber This indicator gives a simple and reliable remote indication of drip-rates, whether the liquid is opalescent or clear

As each drop leaves the drip tube a small lamp attached to the giving set will flash The advantage of the device is that it fails " safe ", as any fault will cause the indicator lamp to stop flashing and so will draw immediate attention to the failure.



The indicator is made up of three units (1) the combined amplifier and battery box, which can be placed at the base of or near the giving-set stand, (2) the drip detector, which is a small plastic moulding, clipped to the drip chamber of the giving set, and (3) the indicator lamp, which can be placed in any convenient position. The drip detector consists of a flash-lamp bulb and a phototransistor so arranged that the beam of light falling on the phototransistor from the lamp is interrupted by the falling drop The pulse signal from the phototransistor is fed into a transistor amplifier, the output from which is used to light an indicator lamp which flashes each time the light beam is interrupted

The light beam is considerably reduced in intensity by opalescent liquids, in clear liquids a sufficient change in light intensity for correct operation is brought about by refraction and internal reflection The length of the output pulse, and hence the duration of the flash from the indicator, is variable and is adjusted by a rheostat on the amplifier box.

The unit contains no moving contacts or relays, and the only maintenance is the replacement of batteries and lamps when necessary A mains-driven power unit can be fitted in place of the battery A separate unit can be plugged into the amplifier box to record the rate of drip over one minute, and the total number of drips given

I acknowledge with thanks the help given to me by G R. Burgess & Co Ltd., Southall, in the development of this useful device, and to Mr H G Jones and Mr D W Allen for their technical assistance. The device is obtainable from this firm, but the price has not yet been fixed as a prototype only has been produced The cost should not be high once the indicator can be produced in quantity.

Reviews of Books

Orthopædics

Principles and Their Application SAMUEL L TUREK, M D, attending orthopedic surgeon, Weiss Memorial Hospital, associate attending orthopedic surgeon, Mount Sinai Hospital London Pitman Medical Publishing Co 1959 Pp 906 160s

Dr Turek's book is probably the largest and most comprehensive single-volume work on orthopædics yet published certainly it is one of the most attractive and easily read Its general plan conforms to that of many similar works There are six introductory chapters on the normal structure and physiology of the skeleton and the connective tissues, and two principal sections which deal with orthopædic diseases on an ætiological and a regional basis Three features, however, set the book apart One is the large number of *illustrations*, including over 50 excellent coloured plates another is the detailed way in which each condition is discussed, with reference to a brief *and* very international bibliography The third is the inclusion of many "medical" topics—such as peripheral vascular disease and the muscle dystrophies—about which every surgeon needs information from time to time This book contains much valuable advice on these disorders, which are not considered at all in many long-established orthopædic texts

It is easy to believe that Dr Turek has, as the foreword states, devoted many years of his life to the preparation of this book, and the product of his labours will be read and admired for a long time to come

In Place of Parents

GORDON TRASLER, PH D, lecturer in social psychology, University of Southampton London Routledge & Kegan Paul 1960 Pp 248 25s

Dr Trasler's book describes an investigation of all the cases of foster care in one local authority's area during a three-year period His study sample consisted of children who had known at least one failure in placement in a foster home, and they were compared with children whose placement had succeeded This detailed study of a limited number of cases not only revealed some of the psychological processes involved but also showed vividly what success or failure can mean to the individual children and parents As the author points out, the observation of children and parents in these somewhat unusual situations can give insight not only into the various difficulties of the people concerned, including the responsible and delicate role of the case-worker, but also into some emotional problems of ordinary parents and children Although he emphasises that techniques of home-finding have progressed considerably in the past two decades, so far comparatively little work has been published on this subject in this country Many of the observations in this book suggest further fields of study, and will surely be of great value to all students and social workers Dr Trasler confirms that the greatest need of any child is some enduring and affectionate personal relationship, a difficult thing to achieve in even the most successful institution Foster care is one answer, and this book will contribute to an understanding of the complications, challenges, and rewards in the whole business of finding and keeping happy foster homes

Cancer of the Breast

Editor WILLARD H PARSONS, M.D, F.A C.S, director of surgery, Vicksburg Hospital Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1960 Pp 232 60s

Dr Willard Parsons and his eleven collaborators set out to provide a concise discussion of the more important aspects of breast cancer, particularly from the clinician's viewpoint They have clearly succeeded in this beautifully produced and illustrated book Their views on the surgery of breast cancer do not differ widely from those of most surgeons in this country, but the chapter on the role of the radiologist expresses doubt on the value of all postoperative irradiation—after either radical or simple mastectomy—a view which would not command general acceptance here

Foote's chapter on pathology is admirable, though one could have wished for more discussion on pre-malignant proliferative changes and sclerosing adenosis Marshall's contribution on the technique of radical mastectomy is also excellent, and Urban adds a very fair and balanced account of his super-radical operation and its results to date It is perhaps the fault of his subject that the editor, in summing up, cannot come out with more definite advice on what to do, despite his undertones in favour of radical mastectomy For a short, readable, and conservative summary of the position, this book is commended

An Atlas of Dental and Oral Radiology

SYDNEY BLACKMAN, M R C S, D.M R E, consultant radiologist, Royal Dental Hospital of London Bristol John Wright & Sons 1959 Pp 384 84s

HERE is a fine collection of 816 reproductions of dental and extra-oral X-ray films covering a wide range of subjects The standard of reproduction is mostly very good, particularly the enlarged apical films, but reproduction of the extra-oral films is more variable Presentation of the films is usually correct—as if viewing the patient directly—but there are a few inconsistencies, particularly with lower occlusal films

The atlas is arranged with introductory discussions to the sections and to some subsections, and the range of headings is wide and generally good The discussions tend to be rather wordy and are not always very informative—for example, the extended one on caries Terminology is sometimes loose, as "the body of the ascending ramus" in the caption to fig 52, and the use of varied terms such as "dento-alveolar abscess", "apical abscess", "rarefying destructive osteitis", and "peri-apical granuloma" is likely to be confusing These are used for what is essentially the same lesion but without drawing any distinction between them or showing in what way they may differ On p 24 it is stated that "the condyles of the mandible are still *immature at 6 months of age*" surely they are still immature at 6 years of age Figs 59 and 63 in the normal section, of a boy at $3^1/_2$ and at 7 years, show the severe reduction in pulp space of all the teeth that occurs *in the* condition congenital opalescent dentine—as is pointed out later in the appropriate section Some points are very well made, such as the diagnosis of neurofibroma and the series of films showing pulp calcification There are no references to the *literature*

The critical reader will find many helpful illustrations of wide variety, but occasional interpretations could be misleading to the uninformed

Peaceful Uses of Atomic Energy (*Proceedings of the Second United Nations International Conference* Vol 22 *Biological Effects of Radiation* Geneva United Nations 1959 Pp 552 104s)—The proceedings of this conference are published in 33 volumes This one covers the biological effects of radiation, but does not deal with health and safety or uses of isotopes as research tools There are 90 papers representing new original work and reviews from most of the larger radiobiological laboratories of the world Of particular interest is the scope of the 19 papers translated *from* Russian, and it is a pity that in these papers it has not been possible to give addresses of the authors (*in contrast* to the papers in other languages) The work quoted is sometimes not given in sufficient detail to convince readers that the phenomena were always properly controlled The opening review by A V Lebedinsky admirably presents the main advances achieved and emphasises the problems still outstanding On p 7 he cites G J Neary and H J Evans as having shown that "The number of primary injuries is reduced in the presence of oxygen" while the authors clearly state the opposite (p 306) "The oxygen effect can be interpreted as an increase in the number of primary breaks " Although this volume is clearly valuable it raises the wider question of the economic wisdom of publishing the results of giant conferences The publication of these volumes has been a great technical feat, and the purchase price probably represents only a *fraction* of the true cost.

THE LANCET

LONDON 23 APRIL 1960

Thrombophlebitis following Intravenous Infusion

THROMBOPHLEBITIS has long been known to follow intravenous infusion The possible causes are several First, the needle may damage the venous endothelium, and accordingly for long-continued infusions polyethylene catheters have been recommended. Secondly, the infusion fluid may be the cause 5% glucose solution is regarded by many as relatively hazardous because of its low pH, though BOLTON CARTER et al [1] found that the incidence of thrombophlebitis was unchanged by using buffered glucose at a pH approximating to that of blood A third factor is the duration of the infusion BOLTON CARTER [2] found that the incidence of thrombophlebitis increased considerably when infusion was continued for more than eight hours A further factor is the nature of the tubing used in the giving set. Until quite recently this consisted of rubber with glass and metal parts HANDFIELD-JONES and LEWIS [3] established that the incidence of thrombophlebitis was influenced by the kind of rubber tubing from which the giving-set was made, the incidence was lowest with pure latex tubing Various reports suggest that when infusions are given through the National Blood Transfusion Service rubber set and continued for more than twelve hours, the incidence of thrombophlebitis may be greater than 50%

In the manufacture of rubber tubing, various compounds are added to promote vulcanisation; and the differences in the incidence of thrombophlebitis associated with different samples of rubber tubing, together with the close correlation between this incidence and the duration of infusion, suggests that a substance giving rise to thrombophlebitis is leached from the rubber tubing through which the fluid passes The use of plastics as an alternative for intravenous infusion sets is not entirely free from danger, for plasticisers and stabilisers added in order to obtain plastic in a suitable form for the manufacture of tubing may be harmful A Medical Research Council trial [4] in which a plastic set and the standard red-rubber set were compared confirmed that the duration of the infusion was important where the infusion lasted less than twelve hours the incidence of thrombophlebitis was nil, but beyond this period it increased appreciably for each set with the duration of infusion With infusions lasting longer than twelve hours, the incidence of thrombophlebitis with the plastic giving-set was only half that with the red-rubber set, nevertheless thrombophlebitis developed in as many as 18% of cases when plastic tubing was used

The toxicity of red-rubber tubing has been assessed by testing its ability to inhibit the growth of *Streptococcus pyogenes* The possible danger of plastics in surgery can be evaluated by implantation into animals; but this is not an effective method of determining early toxic activity. CRUICKSHANK et al [5] have examined the effects of rubber and plastic on the growth of tissue-cultures of chick embryo, the oxygen uptake of skin tissue-cultures, and the growth of *Str pyogenes* It was found that materials which inhibited growth of *Str pyogenes* were also toxic to tissue-cultures, but that some materials which were toxic to tissue-cultures did not inhibit bacterial growth, the latter is a less satisfactory test. Tests of the relative toxicity of materials by the two tissue-culture methods were in agreement. The relative toxicity of the materials, revealed by these tests, could be correlated with the differences in the incidence of thrombophlebitis after intravenous infusions administered through giving-sets assembled from the materials tested, and CRUICKSHANK et al. conclude that "the toxicity revealed by these tests is of clinical importance, and that tissue culture toxicity tests will prove to be of value in selecting rubber and plastics for clinical purposes"

Plastics are used not only for rubber tubing but also for bags in which blood is stored for transfusion In the U S.A. each batch of plastic bags is tested by estimating the survival of cells in blood stored in these bags for twenty-one days at 5°C—the proportion surviving must be greater than 70% A laboratory test which could save the need for such work would clearly be valuable. But the present tissue-culture tests are technically difficult, and we hope that CRUICKSHANK and his colleagues will continue their investigations with the aim of adapting these tests for routine use.

Krebs Cycle

ENERGY required by the body to perform work can be derived from protein, fat, or carbohydrate; but normally carbohydrate is preferentially burned as the main energy source (although fatty acids can also be similarly oxidised) while protein and fat are used for body building and storage respectively Food required for energy is oxidised in a series of steps by which hydrogen is transferred via a hydrogen acceptor (diphosphopyridine nucleotide [D.P.N.] or triphosphopyridine nucleotide [T.P N.]) to cytochrome under the catalytic influence of a flavoprotein The ferric iron of cytochrome is reduced to the ferrous state before another iron-containing enzyme, cytochrome-C oxidase, transfers the hydrogen to oxygen and the process of oxidation is complete. During this series of reactions energy is captured and stored as high-energy phosphate bonds in the form of adenosine triphosphate (A.T.P.). It is now believed that three or possibly four such bonds are generated during the transfer of two hydrogen atoms to oxygen.[1]

Detailed study of the steps whereby the body breaks down carbohydrate has led to the identification of the points at which energy-rich phosphate bonds are formed. Glucose, derived either from the blood or from tissue stores of glycogen, is phosphorylated and then either broken down anaerobically by the classical Embden-Meyerhof pathway to pyruvate or oxidised to phosphogluconic acid and then to the pentose, ribose-5-phosphate. The importance of this last reaction may be in the supply of building blocks for the synthesis of ribose nucleic acid, but evidence suggests that the pentose may also be broken down to a triose which can itself give rise to pyruvate.[2] The proportion of glucose burned in either of these pathways is not known and probably varies in different tissues and at different times. During anaerobic glycolysis glucose gives rise to two molecules of pyruvic acid and four energy-rich bonds are formed, but as one such bond has previously been required for phosphorylation there is a net gain of three molecules of A.T.P.

When anaerobic conditions exist in the tissues—for instance, in active muscle—pyruvate can be reduced to lactic acid, the final stable product of glycolysis, but the energy yield per mole of glucose is poor compared with that obtained by the complete oxidation of pyruvate to carbon dioxide and water via the tricarboxylic-acid or Krebs cycle.[3] Before it can enter the cycle pyruvate must undergo a further series of reactions which convert it to "active acetate", which then condenses with oxaloacetate to form citrate.[3 4], two carbon fragments of fatty-acid oxidation also employ this common pathway.

These reactions might be described as the Achilles heel of the cycle, for they represent the principal point at which a metabolic block may occur. At present at least five co-factors are believed to be necessary to complete the decarboxylation of pyruvic acid—thiamine as thiamine pyrophosphate (T.P.P.), reduced coenzyme A (Co-A-S.H.), D.P.N., magnesium ions, and lipoic acid (6.8 dithio-octanoic acid). REED[5] has suggested that the reactions may take place in the following sequence: pyruvic acid combines with thiamine pyrophosphate to form acetyl T.P.P., this in turn reacts with lipoic acid to yield acetyl lipoic acid, which can then react with reduced coenzyme A to form acetyl Co-A and reduced lipoic acid, the lipoic acid then reforms its internal disulphide bridge by handing on hydrogen to D.P.N., while the acetyl Co-A is ready to transfer the acetyl group to oxaloacetic acid with which it will condense to form citric acid, the starting-point of the Krebs cycle. During this series of reactions three high-energy bonds are generated. Citric acid is a six-carbon, tricarboxylic acid which, under the influence of the enzyme aconitase, forms first cis-aconitic and then iso-citric acid, and the series of reactions then proceeds according to the steps postulated by KREBS.[4] Iso-citric acid is further oxidised by transferring two hydrogen atoms to T.P.N., oxalosuccinic acid is formed, and a further three high-energy bonds are generated. Oxalosuccinic acid loses carbon dioxide to give rise to α-ketoglutarate, a five-carbon acid the further oxidation of which may be another Achilles heel in the cycle. As an α keto acid, ketoglutarate requires the same five co-factors for its further oxidation as does pyruvate and similarly gives rise to the formation of three high-energy phosphate bonds. In addition, ketoglutarate takes part in transamination reactions with both aspartic acid and alanine and may represent the final common path whereby aminoacids enter the cycle to undergo complete oxidation, and it can act as an acceptor of ammonia and probably has a key role in the ammonia-binding mechanisms of the cell.[6] Moreover, in mammalian nervous tissue ketoglutarate enters into a shunt reaction by-passing the thiamine-dependent decarboxylation of the keto acid. After taking up ammonia to form glutamate it is converted via γ-aminobutyric acid to succinic semialdehyde and then re-enters the main cycle as succinic acid.[7] This series of reactions is vitamin-B_6-dependent, and the convulsions in pyridoxine deficiency in man and animals may be due to a biochemical lesion at this point.

From this point the ensuing steps of the cycle may be summarised as follows. Succinyl Co-A, derived from ketoglutarate, gives rise to the four-carbon compound, succinic acid, with the formation of one high-energy bond. The succinic acid is then acted on by succinic dehydrogenase to form fumaric acid and two further high-energy bonds. Fumarate in turn yields malate which, to complete the cycle, gives up a further two hydrogen atoms to form oxaloacetic acid together with a final three high-energy bonds. Thus each molecule of pyruvate is responsible for the generation of fifteen molecules of A.T.P. or thirty such bonds for each molecule of glucose. This is much more efficient than the simple glycolytic process, and any lesion of this complicated and highly efficient system of energy capture may be disastrous to the organ or organism concerned. Moreover, not only carbohydrate but also protein and fat metabolism may be involved. It has already been shown how aminoacids can enter the cycle after transamination, and fatty acids, once they have undergone β-oxidation to acetoacetate, can give rise to acetyl Co-A which then enters the cycle by the series of reactions already described.

The elucidation of the various steps involved in glucose oxidation has given less help to the clinician than might have been hoped. Almost nothing is known of naturally occurring disorders of the Krebs cycle, possibly because breakdown of such an essential energy source would be disastrous to the body. To Sir Rudolph Peters we owe the concept of the "biochemical lesion", and appropriately enough it was his school at Oxford[8] that localised the first block affecting what subsequently became known as the Krebs cycle. This work of the Oxford school showed both in vitro and in vivo that pyruvate and lactate accumulated in the blood and brains of pigeons on a thiamine-deficient diet and that this metabolic defect could be reversed by restoring the vitamin to the diet. A similar block in glucose oxidation was later demonstrated in man, also when thiamine was deficient, giving rise either to beriberi[9] or Wernicke's encephalopathy.[10] Thiamine deficiency might also be expected to interfere with the oxidative decarboxylation of ketoglutarate at a later stage in the cycle, but there is no evidence that this takes place either in vitro or in vivo. Tervalent metals will also block the entry of pyruvate into the cycle, and again we owe our knowledge of this to the Oxford school of biochemists.[11] Arsenite, by combining with the dithiol lipoic acid, inhibits the formation of acetyl Co-A—a reaction which can be reversed by 1 2 dimercaptopropanol (dimercaprol, Bal), which transfers the arsenic from the six-sided to a more stable five-sided ring, leaving the lipoic acid free to carry out the transfer of acetyl groups from thiamine to coenzyme A.

The action of fluoroacetic acid in interrupting the cycle is hardly of clinical interest (although it has been used as a poison by witch doctors to produce the fatal illness "broke back"[12, 13], but it is of considerable theoretical importance, for it gave rise to the theory of "lethal synthesis"—yet another concept we owe to Peters. Fluoroacetic acid enters the cycle in the same way as "active acetate" and condenses with oxaloacetic acid to form fluorocitric acid; this blocks the enzyme, aconitase, so that citric acid itself cannot be converted to cis-aconitate, the cycle is inhibited, and citric acid accumulates in the tissues.[14] The hypothesis that the ensuing convulsions result either from interruption of the energy supplies of the cell or the deionisation of calcium following the accumulation of citric acid has been challenged by Benitez et al.,[15] who demonstrated that in fluoroacetate poisoning a rise in the brain concentration of ammonia preceded the rise in fluorocitrate and exceeded it on a molar basis, reaching its peak at sixty minutes, just before the onset of epileptic seizures. These workers believed that the fits were due not so much to interference with the Krebs cycle as to the accumulation of ammonia. Whichever is the correct interpretation, the action of fluoroacetate in inhibiting aconitase and causing the accumulation of citrate supports current theories on the mechanism of pyruvate incorporation into the cycle. No metabolic lesions are known to affect the steps whereby cis-aconitate is converted to ketoglutarate, but the decarboxylation of this keto-acid is inhibited by arsenite and presumably by other factors which also interfere with pyruvate oxidation. Furthermore ketoglutarate may be drained from the cycle at this point by excess ammonia in the tissues[16], and Bessman and Bessman[17] have suggested that the conversion of ketoglutarate first to glutamate and then to glutamine in the presence of excess ammonia is the fundamental lesion underlying hepatic coma. Whether this reaction takes place in vivo has to be proved, but the brain contains transaminases which can transfer unwanted amino groups to other keto acids with the regeneration of ketoglutarate. Whether shortage of ketaglutarate can act as a rate-limiting step in the cycle also remains to be proved, but blood levels of ketoglutarate have not been observed to fall in the presence of raised values for blood-ammonia. Nevertheless, this hypothesis is of great theoretical interest, and if proved correct it will have provided the first example of a naturally occurring block at this stage of carbohydrate oxidation.

Once ketoglutarate has been converted to succinyl Co-A the reactions taking it on to oxaloacetate can be interrupted only by the selective inhibition in vitro of succinic dehydrogenase by malonate (other less specific enzyme poisons such as fluoride can hardly be considered here). The final step in the cycle—the condensation of oxaloacetate with acetyl Co-A—is probably rate-limiting and must itself depend on the availability of oxaloacetate for completion.

No mention has been made of less well-defined disorders of carbohydrate oxidation, such as the accumulation of lactate and pyruvate in the blood of patients with Cushing's syndrome or on steroid therapy,[18] or of the low levels of tricarboxylic acids in the tissues of diabetic animals, for these abnormalities are believed to be due to a failure of pyruvate oxidation and not to inhibition of the cycle itself.[19] Other conditions in which abnormalities of carbohydrate oxidation have been reported include subacute combined degeneration of the cord, disseminated sclerosis, and schizophrenia.[20] The locus of the metabolic lesion in these conditions has yet to be identified.

As yet no genetically determined lesion of the cycle has been reported, but with the increasing entry of biochemical techniques into clinical investigation it is probably only a matter of time before such a condition is discovered. If the theory of one gene one enzyme is accepted there should be an inherited disorder for each step in the cycle, unless such a fundamental interruption of the energy sources of the cell is incompatible with life.

TREATMENT OF SALICYLATE POISONING

THE complex actions of salicylate in poisonous amounts are gradually becoming more clearly understood.[1] Respiratory alkalosis is probably the first change in most, if not all, cases, but this is followed by metabolic acidosis the causes of which are the acidity of aspirin, interference with carbohydrate metabolism, and renal dysfunction. Metabolic acidosis rapidly worsens as liver glycogen is depleted by starvation and increased metabolism. Besides the problems of alkalosis and acidosis there are those of dehydration, hyperthermia, and potassium loss. Formerly the treatment of severe poisoning was rather unsatisfactory owing to ignorance of these disturbances.

Gastric lavage with water is urgently necessary. (Prof. J. M. Webster[2] stated emphatically in court recently that the prevalent idea that gastric washouts are unnecessary is quite wrong.) Aspirin and methyl salicylate may remain in the stomach many hours before absorption, and it is hardly ever too late to try to remove them. Continuous washing of the stomach is perhaps advisable, as salicylate may possibly be excreted into the stomach or be regurgitated from the small intestine during vomiting. Enemas and cathartics have been recommended in the past—and not without good reason, if the patient is fit enough, for salicylate is probably present in the intestine for some hours and may be eliminated by these measures.

The treatment of the disturbance of acid-base balance should be regulated by blood or urine pH changes. Plasma-carbon-dioxide levels are unreliable because they may be lowered either by respiratory alkalosis or by metabolic acidosis. In the alkalotic stage alkali should be avoided. In most severe cases the patient has a metabolic acidosis by the time he reaches hospital, and this can be well treated with intravenous sodium lactate, or with oral sodium bicarbonate which also increases urinary excretion of salicylate. Overloading with fluid should be avoided, particularly if there are signs of oliguria.[3] Serum sodium and potassium levels should be estimated in order to avoid or to correct hypokalæmia or hypernatræmia. Glucose, given alone or with lactate, is necessary to restore depleted carbohydrate. Hyperpyrexia is prevented or treated by exposure and cold applications. It is wise to give a vitamin-K analogue in order to avert hæmorrhage, and other vitamin supplements can do no harm. Antibiotics, assisted respiration, and physiotherapy are needed in some cases.

Despite these remedies patients, especially children, still die of salicylate poisoning, and it is now evident that one must be prepared to use exchange transfusion, peritoneal dialysis, or the artificial kidney. Rentsch et al.[4] describe the treatment of two desperately ill children, poisoned with aspirin and methyl salicylate, by exchange blood-transfusion. These workers suggest that in children a plasma-salicylate of 40 mg. per 100 ml. is a critical level at which exchange should be considered. Exchange transfusion has all the hazards of massive blood-transfusion but is widely practicable. Intermittent peritoneal dialysis was used experimentally in dogs by Etteldorf et al.[5] The inclusion of albumin in the fluid used for dialysis resulted in the removal of large quantities of salicylate; the albumin, which binds salicylate, was supplied as plasma or 5% human albumin in iso-osmotic buffered diluent. This method might be worth trying in man, but the risk of infection may be far from negligible, and specially prepared fluids would be required for good results. The artificial kidney is probably the most useful method, and the help of a team operating a kidney unit should be sought before it is too late. The main drawbacks are technical difficulties in infants and children and the possibility of incompatibility with blood used to prime the apparatus.

SMALL ARTERIES IN HYPERTENSION

HYPERTENSION may precede any evident changes in the kidneys.[1] Exactly where, how, or why the condition starts is still a mystery, but the blood-vessels, particularly the arteries, are obviously involved. D. S. Short, after his success in demonstrating diffuse narrowing of the small arteries of the lung in pulmonary hypertension,[2] has, with A. S. Thomson, tackled systemic hypertension with postmortem investigations on the vessels of the small intestine in a small series of cases.[3]

After injection of the superior mesenteric artery with a radiopaque medium at a pressure of 150 mm. Hg for normals and of 200 mm. Hg for hypertensives, radiographs and histological specimens were compared. Only cases in which all arteries down to a diameter of 20 µ were completely filled with injection material, and in which there was no longer any crenation of the internal elastic lamina, were used for evaluation of the submucosal plexus of vessels. The larger jejunal and ileal branches were more tortuous in cases of hypertension than in controls, the next smaller size of vessel—the vasa recta—showed more difference in calibre with age than with blood-pressure, while only 3 out of 8 cases with hypertension showed significant increase of cross-sectional area indicative of medial hypertrophy. The main findings were that the number of smaller arteries (i.e., those of the submucosal plexus and especially those with a calibre of over 70 µ) was significantly less (about half) in the cases of hypertension than in the controls, and the thickness of the walls was about the same, thus excluding any medial hypertrophy or intimal thickening. From these results Short and Thomson conclude that the arterial narrowing in systemic hypertension is due to a reduction in the distensibility of the arteries, by unidentified structural changes in their walls.

Morlock[4] showed that the walls of arteries in the pancreas, liver, spleen, and gastrointestinal tract in cases of hypertension had an increased thickness in relation to the calibre compared with controls. Short and Thomson postulate that this altered ratio may have been due either to hypertrophy of the vessel wall or to arterial contraction causing reduction in calibre without any change in the structure of the wall, and they believe that their own investigation by fixation under pressure has shown that the latter is the correct explanation. The characteristic changes of established hypertension in the vessel walls,[5] especially the hypertrophy of muscle-fibres in the media and the very noticeable reduplication of the internal

elastic lamina, were not present in Short and Thomson's cases (unfortunately the vessels in other organs, such as the spleen and kidney, were not also examined) Does this mean that in these cases the intestinal vessels had evaded the usual changes or had not yet succumbed to them? If this is so, Short and Thomson have proved their point for early cases—possibly at the stage where drugs can still control the hypertension[2] Investigation of a larger series of cases and more organs would be helpful Confirmatory evidence might be obtainable by an in-vivo test to show that the volume of blood in the small arteries is less in proportion to the total volume in hypertensives than in normotensives In later cases, with definite changes in the walls, Short and Thomson's technique might be used to study the effects of increased pressures on various combinations of muscle, elastic tissue, and collagen, as was done on the skin by Dick,[6] who showed that where the proportion of large elastic fibres was high there was a lower original tension and less resistance to stretching than where the proportion of collagen fibres was higher and elastic fibres were shorter

INTRACRANIAL ANEURYSMS

THE surgical treatment of intracranial aneurysms has been much discussed, but rather less attention has been given to their morbid anatomy and pathogenesis Professor Crawford[7] has corrected this deficiency He studied by careful dissection 163 ruptured aneurysms and 40 unruptured ones In 20 cases of ruptured aneurysm a second, unruptured, one was found He considers that once an aneurysm forms it tends to enlarge slowly but relentlessly, and, as it becomes larger, it usually becomes irregular in shape, often wrapping itself round contiguous vessels and nerves, hence it may superficially appear to have a broad origin from its parent artery when, in fact, its neck may be quite narrow The one factor which may check the progressive enlargement of an aneurysm is extensive thrombus formation within it He found that aneurysms tended to rupture when they had reached a diameter of 6–15 mm, but occasionally a minute aneurysm ruptured with an appearance as if a hole had developed directly in an artery

In view of the development of surgical treatment of ruptured aneurysms, Crawford made a special study of the common sites of rupture. Of 163 cases rupture took place in the fundal third of the aneurysm in 64%, in the middle third in 10%, and near the neck in 2%, while in 24% the site of rupture could not be established In many cases rupture took place by the bursting of a very thin-walled "bubble" on the surface of the aneurysm, but where thrombus had formed in the aneurysm, blood might dissect up between the thrombus and the aneurysmal wall until it reached the fundus and burst through the ill-defined degenerate collagen-like layers there

Crawford, reviewing the pathogenesis, points to two factors which make the cerebral arteries especially prone to the development of aneurysms first, the thinness of the media compared with that of other arteries of comparable calibre, such as the coronaries, and secondly, the poor development or even absence of the external elastic lamina. He confirms previous reports of developmental faults in the media, especially at arterial junctions, and emphasises that in such cases the continuity of the arterial wall may depend largely on the internal elastic lamina He also indicates the importance of atherosclerosis in conjunction with a developmental defect in the media Besides thinning and fatty infiltration of the media, degeneration of the internal elastic lamina often develops at the base of an atheromatous plaque, and when atheroma develops at a site on the artery where there is already a developmental defect in the arterial wall, the wall will be weak and aneurysmal dilatation very likely

ESSENTIAL TREMOR

THE complete and reliable demographic data in the Swedish parish registers, extending over several centuries, have provided a magnificent opportunity for combining the genealogical with the mendelian approach to genetically determined conditions The isolation of certain areas, persisting to some extent even today, has given the conditions both for the emergence of unusual concentrations of some inherited disorders and for tracing the steps in their appearance Professor Torsten Sjogren, head of the department of psychiatry at the Karolinska Institute in Stockholm, has thus studied several neuropsychiatric disorders, and Larsson and Sjogren[1] have now described an investigation into essential tremor This condition has been surveyed previously by several workers, notably by Critchley[2], but the material, collected in hospitals, was largely selected, since a patient with a disease known in his family to be unresponsive to treatment seeks medical advice only when the manifestations are unusual or the disorder is complicated by some other illness

An inland parish in Northern Sweden, earlier studied with regard to the prevalence of oligophrenia[3-5] and psychosis,[4,6] was chosen because of the high frequency there of essential tremor 81 people with this disorder were examined, and extensive information was obtained about affected and unaffected relatives The average age at onset was 50, with extremes in the second and eighth decades The initial symptom was a fine rapid tremor which over the years slowly became more pronounced and tended to spread in those more severely affected to involve the tongue, head, arms, legs, and trunk Nearly a fifth of those examined had some rigidity of the limbs and stiffness of gait, but there was no akinesis or other features of parkinsonism There were no associated psychiatric changes, nor was the morbidity risk for other neuropsychiatric disorders increased Fertility and mortality did not differ from that found in the local population

Genetical analysis indicated that the condition was inherited as an autosomal dominant, and there was no suggestion that those presumed to be homozygous for the abnormal gene were more severely affected than the heterozygotes Persons carrying the abnormal gene were estimated to amount to 8–9% of the population of the western part of the parish studied Genealogical research showed that all cases seen, and all their affected dead relatives, had lines of ascent to one or more of nine ancestral couples, and that all cases save 2 could be explained by dominant heredity from four of these couples born during the second half of the 17th century, three of whom belonged to the parish under investigation and the fourth to a nearby parish It therefore appears likely that in all the patients the disorder was derived from a single ancestral couple about four hundred years ago. Because of the genetic unity of this series, the conclusions drawn from it may not all be applicable to other patients with essential tremor, in whom it may possibly be due to a different mutation, but, their series being unselected, Sjogren and Larsson have been able to make a most valuable assessment of the variability and course of at least one form of this condition.

FOOD-POISONING

MEDICINE is international, but medical education, the conditions of practice, and even the fundamental emphases of pathology are not. Hence there are disadvantages as well as advantages in the kind of international report which the World Health Organisation so often produces. The experts assemble for a few days or weeks, they work hard to discover the highest common factor in their ideas, they conceal their very obvious differences, and they have to produce a statement. Not unnaturally the result is sometimes a minim of facts diluted in an ocean of truisms. The report of the European Technical Conference on Food-borne Infections and Intoxications,[1] for example, gives us 16 pages on the classification of food-poisoning, its detection and notification, and some measures for its control, but there is nothing new in it, and collaboration has lowered instead of raising the level on which these authorities write. Incidentally, it does not mention one of the most pressing dangers in the international trade in food—the use of organic phosphate insecticides on fruit and vegetables.

Meat and eggs from continental Europe have played a small part in causing food-poisoning in Great Britain and have introduced a few species of salmonella hitherto unknown here. Similar introductions have no doubt occurred in other countries, but of this we have no evidence. Are we receiving the overflow from some great epidemic—as we do of foot-and-mouth disease or Colorado beetles—or is this an example of a slow and continuous spread of infectious agents which do not regard political boundaries?

The answer may be derived from the better reporting of food-poisoning, which, as this report hints, might be more complete and more accurate everywhere. In England we are probably better served than in most countries. Our medical officers of health are responsible for relatively small areas, our laboratory service is adequate, and no-one lacks medical attention because of his poverty. Most outbreaks of food-poisoning in institutions and communities are known, and they are often investigated thoroughly. But the reporting of individual and familial infections (which may be just as important to the epidemiologist) is less satisfactory, for two reasons: many adults do not seek medical advice for an ailment which does not send them to bed and which upsets their lives less than a severe cold, and many practitioners do not report a disease which appears to affect only one or two and which (in most instances) cures itself. If we with all our manifest advantages fail in reporting all cases of food-poisoning, we cannot expect any better from poorer countries where doctors and laboratories are few, where such diseases as enteric fever are still endemic, and which have tougher populations that seek medical attention only in dire necessity. In these less fortunate countries a good deal has been learnt about some other diseases by the intensive study of a sample of the population. The report does not mention these methods, which might tell us more about the prevalence and origin of food-poisoning than the sporadic and incomplete returns from a whole nation.

Despite tariffs and quotas the international trade in food within Europe is considerable. Dr Hobbs and her colleagues have shown that the bacteriological examination of imported food can reveal dangers which had not been suspected.[2] Yet it may be easier to sample imported than home-produced foodstuffs. We may see the day when the sanitarian replaces the customs officer at the frontier (or maybe the frontier itself will disappear), and meanwhile there is much to be said for an international agreement for the sampling of imported foods and the tracing of infectious agents to their origin. On the whole, however, food-poisoning is not a subject which encourages useful international action. The need for international measures may be clear to the experts, but it is not yet so obvious to the many other parties interested—the veterinarians, agricultural, transport, wholesale and retail trades, and the consumer. The technical problems are the least difficult to solve: the hardest in all countries is to persuade the public that some action is necessary.

STATUTORY SANCTIONS?

IN preparation for its move from Pall Mall East to Regent's Park the Royal College of Physicians has presented a private Bill to Parliament[3] to modify and modernise some of its ancient rights. It seeks approval to hold meetings "anywhere in England", instead of, as at present, only in Westminster or the City, it seeks to be allowed to hold land of an annual value exceeding the present limitation of £1000, and it seeks formal authorisation for its name, which, though used in the Medical Acts since 1858, has not appeared in many of the college's own legal documents.

At first, or indeed at second, sight the Bill does not seem controversial, and it has passed without comment or incident through the House of Lords. In the Commons, however, its progress has been blocked by a motion tabled by Dr Barnett Stross, supported by Mr Kenneth Robinson, Dr Dickson Mabon, Miss Margaret Herbison, Mr Ellis Smith, and Mrs Harriet Slater. When the Bill was called for a second reading on April 12 Dr Stross again objected, and the second reading has now been deferred till April 26 when it will be debated.

To *The Times*[4] the group have explained that their motive in hindering the progress of the Bill is "to get changes in the by-laws of the college so that Fellows and members will have a more effective voice in the affairs of the institution." On this subject they seem to be imperfectly informed, and even those who may sympathise with their aims will hardly condone the means they are adopting. The constitution of a learned body and its methods of conducting business are a domestic and professional matter. To attempt to intervene by exerting legislative pressure is a misuse of parliamentary procedure.

SIR ROBERT PLATT has been re-elected president of the Royal College of Physicians of London.

HUMAN RELATIONS IN OBSTETRIC PRACTICE [*]

NORMAN MORRIS
M.D Lond., F.R.C.O G
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF LONDON AT CHARING CROSS HOSPITAL MEDICAL SCHOOL, W C.2

DURING the past twenty-five years changes in obstetric practice have reduced the physical hazard of childbirth dramatically This achievement has tended to make us a little complacent. Indeed some people even suggest that there are few problems in obstetrics left for us to solve. But are we to measure success simply in terms of life and death? Though the physical care of the patient has advanced, I believe that many serious gaps remain, particularly in our knowledge and understanding of the patient's emotional condition in pregnancy, labour, and the puerperium.

For most women childbirth is their moment of greatest achievement and sometimes of greatest happiness It is an immensely important emotional as well as physical event. It is a period of great intensity of feeling and reaction. The influences that a woman meets during this time may have a tremendous psychological and social significance, and in my view our present hospital system often fails miserably in its care of the patients' emotions The joys, hopes, and wonder that the arrival of new life should bring are spoiled, and splintered into loneliness, indignity, and despair The feeling of personal achievement is lost, drowned in a sea of inhumanity

My own opinions and observations have lately been reinforced by a collection of extracts from several hundreds of letters sent to a weekly women's journal,[†] which I have been allowed to study

ANTENATAL CARE

Antenatal Clinics

Women attend these clinics regularly, often as many as fourteen times The clinic is usually drab and colourless, painted in bottle green, brown, or dirty cream. There are rows of uncomfortable benches There is an atmosphere of coldness, unfriendliness, and severity more in keeping with the spirit of an income-tax office. The clinic is often very overcrowded, and at best a crude appointment system is in operation. Despite this, women often wait 1-3 hours The interview itself is usually extremely brief, and under such conditions there is little encouragement for the patient to ask questions or relieve herself of any nagging fears or doubts Therefore she often remains in gross ignorance of what is happening to her The doctors and nurses also remain virtual strangers since she rarely sees the same one at each visit.

The following extracts from the letters describe experiences in antenatal clinics

"As you entered the doctor was already reading your case-sheet, and we were on and off the examination table in two shakes barely two minutes, when we had waited perhaps two hours or more I did meet one mother, who was on her first visit only three weeks before her baby was due. She had other children who she found it difficult to leave for so long a time. There was no system of appointments "

"The nurses and doctors were very friendly at the antenatal clinic and very helpful—but—we were rather like 'sausages in a sausage machine' I understood that there were far too many pregnant women and far too few doctors It was rather amusing to hear the remark of a nurse on seeing one mother-to-be making her face up She was told 'Don't bother with your face, dear, it's the other end he's interested in'"

"The midwives at the hospital all seem to have too much on their plate to bother with the odd person who wants to know 'why, where and what' Whenever I go for treatment, it always seems as though I were being put on a conveyor belt and passing through all the different stages—water—blood—examination and out. There seems to be nothing human in them at times"

"I am not wanting to be fussed over, but I do think a friendly reception—with a smile would go a long way to make one feel more confident about the birth One's reception is so cool, and there seems to be little interest shown at hospital, with hardly an exchange of words In fact these seem to be minimised to 'Go in, undress, lie down' (from a very tight-lipped nurse) and 'Are you feeling any kicks?' (from the gynæcologist) More often than not, I feel like giving him a few kicks myself!"

There is a myth that patients will not keep appointments This is not true. Appointments will be kept by the patient, if the hospital shows definitely that it intends to honour these appointments on time. Doctors interviewing large numbers of women on an endless conveyor-belt system inevitably lose their sensitivity Not long ago I heard a senior obstetrician admit that even after seeing about eight patients he began to feel dizzy Such an arrangement is terribly fatiguing, and yet there is little evidence that much is being done to end this archaic system

Preparatory Classes

Many hospitals encourage some form of classes for special instruction and preparation for labour, but unfortunately there is often poor liaison between the people who run the classes and the staff of the labour ward. Few obstetricians take an active part in organising and running the classes, though physiotherapists and midwives are doing excellent work despite our lack of support

Virtually no studies have been done on the average patient's emotional response to pregnancy and labour. We know even less about the ultimate effect of experiences in childbirth on the mother's relationship with her child and family As a result these preparation classes are very much in their infancy But even in their present form they do enable women to approach labour with confidence and to bring it under their own control In my view a hospital that fails to provide such classes is as negligent in an emotional sense as it would be in a physical sense if it failed to test the urine regularly during pregnancy

Some obstetricians and midwives still doubt the value of preparation classes They point out that preparation has no effect on the length of labour, the forceps-rate, or the cæsarean-section rate. They are obsessed by purely physical standards How can we produce statistics to show how many women emerge from labour exalted rather than demoralised, confident rather than afraid?

---

[*] Based on a lecture given at the opening of the new obstetric unit at Charing Cross Hospital on Feb 23, see *Lancet*, March 5, 1960, p 556

[†] The original letters are available in the offices of the journal, but I have been sent only extracts, and I do not know the name and address of any of the patients or their hospitals

We can measure the length of labour but not the mother's sense of achievement or wellbeing

MANAGEMENT OF LABOUR

When the patient arrives at the hospital in labour, she usually goes through a ceremonial, known as "being admitted" Before this ceremonial can begin she often has to supply "some particulars" to the porter or nurse on duty She is then undressed, shaved, given an enema and a hot bath Some more active centres also treat their patients to a castor-oil cocktail These measures can prove a little unnerving, especially if they are unexpected When this ritual is completed the patient either goes into a first-stage labour-ward or into the general ward

In the first-stage ward, usually a large room with several beds, there are often many women in different stages of labour To a woman in early labour it is extremely frightening to be brought into such close contact with women in the later stages of labour and who may appear distressed and upset

The following extracts show how much sympathetic management can contribute to the patients' morale

"Then came the hustling process into a bath, then an enema, with my mental condition indescribable! I thought all this might injure my baby and they could not be bothered to offer the one word of comfort or explanation. From 7 A M till noon I did not see a soul, and was told before being left on the labour bed 'Don't keep ringing the bell, we have not the time to answer you' Eventually, my son, an eight pounder, was safely delivered, but I had been robbed of my peace of mind for many months to come In fact, to be frank, in my youth and ignorance, I could not bear my husband near me for a long time after the baby's birth "

" I am a young girl of twenty-one and I had my first baby a little over two months ago I was in labour for two days and nights, and was on my own for the whole time, except for occasional heads being popped round the door, and when my husband could come I had to lie in pain listening to other women groaning and calling out in pain all down the corridor I was very very scared! During the last few hours, after calling for a nurse for considerable time, she came bustling in and told me to 'shut up' and what did I expect when I was having a baby—of course I was in pain' She then plonked the gas and air machine on my nose, told me the baby would not arrive for ages—and left me"

"Later in the night or early morning, another mother was admitted to the same ward and had her baby with just a screen between us I was sweating with fear for my forthcoming labour, and it was probably far worse just to hear the sounds and not know what was happening After this experience my own contractions stopped, probably due to fear"

"The first baby was born in hospital, the second at home And the third will be at home I found that in hospital they are more concerned with the second stage of labour than the first The reasons may—in fact most probably are—due to shortage of staff, but to a woman giving birth to a baby—a first one in most cases—it is extremely terrifying to be left alone I believe the staff in a maternity ward leave the women on their own for the simple reason that they do not know or understand how lonely they are Shouldn't part of their instructions be the state of mind of a pregnant woman, as well as her body ?"

"Why not make an appeal to women who have had at least three children, to volunteer to sit with mothers in labour wards of the busy maternity hospitals ?"

"I had a midwife my age and two nurses present at my daughter's birth, and they were wonderful We all worked as a team, and I can't speak too highly of them My baby cried when her head popped out, and we all laughed, and suddenly the lump that I had in my tummy became a person She was there and she was mine, and I was full of beans and wanted to rush around to all expectant mums to tell them not to fear, put themselves in the hands of their doctors and nurses, and enjoy the most wonderful experience of their lives"

"It is the adult approach that appealed to me personally To be told encouragingly 'you are doing fine with your breathing, everything is coming along nicely' and 'now the second stage is starting, baby will soon be born' You feel marvellous, as if you are part of the team, and they are rooting for you!"

"Looking back, it does seem to me the worst of childbirth is that the nurses and doctors tend to forget that you are the body through which life is coming into being, and that you want to be kept in the picture"

Some obstetricians and midwives still do not allow husbands to be with their wives during any stage of labour Here are some more patients' views

"Every woman realises that her husband is rather apprehensive the first time when he knows that his wife wants him with her, but it means secretly a lot to a woman that he did not choose to shirk what she could not shirk either"

"My husband said, a few hours after our son's birth—I cannot imagine life without him now, he seems to have belonged to us for ever, seeing him born made him belong to me, too, whereas, when you came home from the hospital with Sarah, she was a little stranger, and I found it hard to realise that I too had a place in her life"

"As for having one's husband at the birth, that's nonsense Most men couldn't stand it, and that's a fact My husband was visiting me when labour started, and I thought he would never go away and leave me to it I can't be bothered with anyone during labour In fact, I usually doze until it's time to start pushing"

If a husband wants to be with his wife in labour, I am certain that we have no right to deny him this experience I actively encourage husbands to be present providing they know what to expect

The following extracts describe the mothers' reactions after the baby has been delivered and in the puerperium

"When at last I got to the ward, I thought I should see my baby, but they just said, 'he's all right, you'll see him in the morning' Eventually one sympathetic staff nurse carried him round the ward and I saw him in her arms, but I still didn't have him to hold myself until the morning after he was born (he was born at two in the afternoon) All the ten days I was there, I only held him for a short while for feeding and when I eventually got home, it was some while before I felt he was really mine My husband, too, had only seen him at a distance, he felt stranger than I did!"

"After each feed in hospital we were expected to express any milk remaining in the breasts, and woe betide us if, when the bowls were handed in, we had not contributed something It was common practice for the midwife to take the mother's nipple between none too gentle fingers and to painfully extract such milk as remained in the breast I don't condemn this practice, which seemed to help the breasts from becoming too heavy and painful, but I do object to the manner in which it was carried out The hospital was modern, efficient, bright and cheerful, but we might indeed have been cattle—and rather tiresome cattle at that I have no doubt that the nurses and midwives were overworked and the hospital understaffed—and perhaps in these conditions it is hard to be patient with mothers, who, after all, are not ill"

"The nurses should remember that although they are used to the sight of the human body, to many young women, childbirth is their first experience of hospital, and they are extremely shy of exposing themselves"

DISCUSSION

These extracts are only a small sample of the many views which were expressed in the different letters Perhaps I have painted the picture in too harsh colours, but I feel that if we are really honest, we must admit that there are times when the atmosphere in our maternity units is not very pleasant The recurrent theme of the letters is lack of rapport between the hospital staff and the patient, and we should do well to consider the reasons for this

Why are some women left alone in labour and often shown very little kindness and sympathy? Why is there so little thought for the mother as an individual? How far is this situation the end-result of poor training and can it be prevented? Is this unsympathetic attitude a form of defence mechanism against the constant load of anxiety inevitable in every maternity unit? Is it also related to the fact that midwives have to work very hard for long periods under stress, and have to spend valuable time on domestic chores rather than on the actual care of the patients? Nurses in training always seem to be walking about and are seldom encouraged to sit down and talk to their patients Does this also contribute to the later development of an inhuman attitude?

Why do some hospital doctors appear cold and distant? Are they overworked or badly trained? Do obstetricians in training have enough opportunity to learn much about normal labour and do they develop much insight into women as women? Has the physician-accoucheur been replaced by the surgeon-accoucheur with little interest in normal labour? Do our senses become dulled by constant observation of childbirth? Are some people's reactions to childbirth subconsciously different from what they appear to be on the surface? In fact, do some nurses and doctors find childbirth repugnant and not something rather wonderful? Do midwives who are spinsters past the menopause have to contend with specific emotional complications, which in part are exacerbated by their occupation?

How far are any of us fully aware of the impression we make upon the patient?

Major conflicts do often exist between midwives and doctors, midwives and midwives, and finally between trained midwives and pupils It is useless for us to pretend any longer that these conflicts do not occur Does the present training as laid down by the Central Midwives Board really encourage the idea that midwives should cooperate fully with doctors in the joint management of normal labour, or do the present regulations tend to encourage the midwife to think that she is entirely responsible for normal labour and need only call in medical aid (doctors) when things are going wrong? What other factors have resulted in doctors not being present during, or in control of normal labour?

Do the present training methods ensure that matrons, superintendent midwives, and sister-tutors have adequate knowledge of psychology and of the enormous influence that they may have for good or ill on young pupil midwives, who are often coping with emotional difficulties and complications of their own? In fact, should there be an "agonising re-appraisal" of all the present methods of training midwives and obstetricians?

Surely it is not necessary to know the answers to all these questions before we make some attempt to put our house in order First, all hospital staff must appreciate that the mother-to-be is extremely vulnerable She is at their mercy for good or for ill Many of our present procedures, which involve dragooning and regimentation, must be revised The training of nurses, medical students, and midwives must include a careful study of patient-staff relations and also exactly where these are likely to break down The importance of *words* and their impact on the patient must be repeatedly emphasised—in particular the extraordinary value of kindness

We must destroy the illusion that the patient is a human being apart, someone quite unlike ourselves We must get rid of that awful method of dividing patients into "cooperative" or "uncooperative", into "easy" or "difficult" This classification is largely based on how much regimentation the patient will stand without complaining

I have an enormous respect for the great work that midwives are doing, and the huge burden they are carrying, but I am conscious that there are a few midwives, just as there are doctors, who do let the side down badly All midwives and doctors, particularly those in charge of labour wards, should have a proper insight into the emotional as well as the physical needs of their patients and staff We must somehow ensure that no patient is ever at the mercy of a midwife's own frustrations and mixed-up emotions No senior sister must be allowed to exert her authority by means of a reign of terror, to which even the consultant obstetrician himself sometimes submits

We must replan our maternity units, so that every department reflects joy rather than sorrow, hope rather than gloom, life rather than death Somehow we must contrive to reproduce in hospital the natural tranquillity that often develops quite spontaneously with home confinements Architects must combine with us to experiment in new forms of design

We must also resolve the conflicts which often exist between midwives and doctors An obstetric unit must operate as a unit and not as a collection of jealous individuals The division of obstetrics into "normal" and "abnormal" can only do harm, since obstetricians have come to concentrate their attention more and more on the abnormal As a result so-called "normal" labour is taken for granted and is conducted on a rule-of-thumb conveyor-belt system Obstetricians should take much more active interest in the direction and coordination of their units, for a maternity unit is a complex organisation, which calls for continuous leadership and example. Each unit must be encouraged to develop its own philosophy and sense of purpose Obstetricians were not meant to be reluctant foremen of baby factories, but privileged guardians of the next generation

If we can use pregnancy as a time of preparation, not only for labour but for all that family life means, and if we can make childbirth a more positive experience, then I think the social repercussions will be remarkable. The next century will undoubtedly see a great advance in our understanding of all the complex factors that influence and govern human relationships The health, happiness, and possibly even the survival of our children will depend on the success of our studies in this field Midwives and obstetricians have an especial responsibility, for they are there at the beginning, and probably it is the manner of the beginning that matters most of all.

The Widdicombe File

LX.—ON AUTHORSHIP

DEAR GEORGE,

I said I'd tell you how to get a paper printed, and do it I shall There are two approaches and I'll give you the most dangerous first "27-Oxyhydro-10 Propolapine and its Linkage with an Aliphatic Chain in the Gunner-Bungstadt-Freundloichter Syndrome" You'd think you would be safe with that (this is for the glossy magazines, by the way, the ones which come flat), but somewhere there will be an expert on 27-0-10-P and he'll want to know how you got the aliphatic linkage when he always uses a hydroxyl grouping It's no use returning his letters with "gone away" or "do not wish to join" when he tracks you to St E's you'll have to lock yourself in the lavatory So we'd better get back into the "popular price" class, as the motorcar people say

What about "Steady Increase in the Number of Two-Headed Men seen at an Outpatient Clinic in the South London Area"? You'll have the field pretty well to yourself, and other two-headed doctors (I mean one-headed doctors of two-headed people) will be cheerful extroverts Subsequent correspondence with them will be chatty and gossipy You'll have fun with the record companies who'll want you to form close-harmony groups (four for the price of two)

You rather like this one? All right Your facts and figures are marshalled (including those who didn't come back but should have) and you are now ready to communicate with an anxiously awaiting world

The original title is a bit long What about "Increase in the Number of Two-Headed Men in the South London Area"? This is nicer but it might not be quite true Perhaps the population is steady and more are coming to the clinic What about "Two-Headed Men"? The papers would call this a banner line, and it has the impact (slightly subdued) of "Blonde Slugs Cop With Bottle" which I saw in New York before the war

Now comes the framework of the paper If you don't rough it out beforehand you may get the results mixed with the method, and other combinations which will give the thing a "jumpy" feel

Next the introduction—the "why" of the paper "*My wife won't let me watch Wagon Train and Gun Law on the telly, so I am writing this paper on two-headed men so that she will see my suffering and relent*" This, of course, might be quite honest and will get you the manuscript by return, a gold medal from the editor with his sincere admiration for the truth, and a visit from a psychiatric aftercare worker So you can cut out the family life bit Normally the introduction leads from the title into the body of the paper I notice that occasionally a piece of the discussion strays into it and sometimes the two are *combined* I suppose this is permissible if it more fully describes what the paper is about, but I prefer to bare my soul at the outset and let them have the facts and figures early on

The next phase is material and methods If you intend to write a series of papers these will have to be described in detail in the opening number and you can refer back in subsequent productions Whether you include them or not in your final copy, subheadings are essential in your earlier runs It will let you visualise the paper throughout Clinical Material describes what you are working with

"The patients formed a group seen at a special outpatient department serving a general population of 100,000 in the South London area"

What you did with them will come next, under Clinical Methods

"The patients were interviewed by the almoner at first attendance and an individual punch card was made out on which were recorded weekly, weights, blood-counts, and gastric acidity findings"

Now comes Laboratory Methods

"A sample of bile was obtained from each patient by duodenal intubation when first seen and weekly thereafter for three months These were stored in the cold cabinet of a domestic refrigerator until the completion of the investigation when they were tested by the method of Jekyll and Hyde (1950)"

I now use Clinical and Laboratory Methods as one subheading, and include in it material and clinical and laboratory methods It saves space and it seems to read quite clearly

And now comes the meat of the paper—what you found This should be subtitled *Clinical Findings*, or *Results* if you prefer Graphs should only be used if they assist clarity and you should be able to save space in the description But a clear table of results makes the paper easy to read and is handy for reference The same holds good for laboratory findings, which usually tabulate well

Now for the Discussion You can let yourself go a bit here as you have been somewhat Spartan (as you should) in your material, methods, and findings Discuss the background to your paper more fully, and bring in similarity or otherwise to previous investigations with the references Having done so, lead on to what you think has been suggested or proved from your paper, and there you are This last bit is sometimes subtitled Conclusions, but I think the reader will draw his own conclusions and you should always underestimate the importance of your findings rather than otherwise

The Summary, which comes next, is a bare-bones recapitulation of the facts and findings Nothing new must be added Acknowledgments now follow, and there can be very few papers which are the sole unaided work of one man A word of thanks to those who helped is not out of place

References come last, and use as few as possible If you are writing a thesis or a book, then of course you will try to include everything which has a bearing on your investigation

Well, George, these are the "Easy *steps to author-ship*" and they would apply equally to a short paper or a book I find it useful to have the references *before me* at all times, and I got our carpenter to put a large notice-board in the office on which I pin abstracts of relevant papers It saves shuffling through a file each time you want something

Now let's get right back to the beginning and commence the actual writing There is a tendency which we all share when writing for publication to be somewhat *pompous* and prosy "We have been reluctantly forced to the conclusion after careful and prolonged *deliberation that*" —which only means "We think" or "It seems" Semantics is the science of the meaning of words, and the reader should know what you are saying at *first pass*

So keep your writing simple The sentences should be fairly short and should follow each other smoothly Remember you are not reporting a prize-fight

"Have seen 80 cases G B.F syndrome given one half 27-0-10-P, the other half chalk half with 27 &c O.K , other half gone useless writing am changing name and leaving country"

As regards punctuation don't bother about it too much Get the periods in as you write and you can deal with the commas later

Some people still write in longhand, but for many years I have typed the papers from the first copy, otherwise I have no idea what it will look like in print If you are writing with a pen, feed it to your secretary as you finish each page. You will get the feel of it earlier and it will save space on your desk.

Let's suppose you have finished the first copy and you are wondering whether to burn it or plug grimly on. What about your figures, don't you think a statistical analysis would be a good thing? This is where you meet statisticians for the first time, and there's quite a technique for this At first contact you will be asked if you use the χ^2 technique, and you will answer simply (and truthfully) "I dunno, I never was any good at sums" You will then find them very pleasant, and as a rule they won't knock the figures about much Their advice is helpful in the preparation and presentation of tables

That's another hurdle behind you. Still want to go on? I know you hate the sight of the thing by now Already you are on conversational terms with trees, birds, and telegraph poles in public transport your lips move soundlessly and you don't seem to have much recollection of how you get home at nights But there is one other thing I must mention and that is tense When your nerves have calmed a bit go through the paper and see you are not switching from past to present perhaps better still, get someone else to do it to whom the paper is new On the whole it's better to keep everything in the past tense.

Now the paper is finished and this is the next essential move. Put it in a drawer and forget about it for a month or two All papers improve with ripening, and this is the time for you to get out and about, meet people, ignore the birds Some time when you have recovered, get the paper out and go through it with a black wax pencil Don't be frightened, it will have to be retyped about ten times anyway Cut, cut, and cut each time You say there will be nothing left, but a small diamond is better than a ton of household coke, so get in there and slash

Dawn follows the night and you are now coming up for the final retype By this time your secretary will have resigned three times and no-one has smiled for weeks, but this is the copy which must be perfect Feed it to her a sheet at a time and go through it with a comb for spelling and punctuation Keep two copies yourself Sometimes you can erase a spelling error without altering the appearance of the sheet, but if it looks messy have it retyped Remember, at every retyping there's a chance of a spelling error creeping in Double spacing, by the way, with a good margin. At this stage I detach a copy of the references and get our librarian to check them He also abbreviates the titles of the journals for me

And now here it is at last A slim edition of its former self (and much better too) Keep it in an envelope, it looks better without dog ears and teacup stains I post my MS flat in a foolscap envelope and clip a short letter to the editor on the front

Suppose all has gone well your article is accepted, and the great day comes Let's follow *The Locust* into a typical medical household It's father's day for the atomic space gun, and from behind his coffee he's having a surreptitious shot at the fireplace to see if it really disintegrates, mother is looking wistfully at the incredible figures in *Vogue*, and young Alfie is taking swipes at his brother with *The Locust* until told to "put it with your father's other medical magazines" (in the toolshed), and there it stays until the next Comanche raid by the redskins across the road It's a very handy size for frontier warfare In the seats of learning a few may tick it for future reading and fewer still may actually read it after a glance at the summary A very (very) few may be interested and may actually ask you for a reprint Now I am firmly of the opinion after careful and prolonged (Good God, I'm doing it too)—well I think that all these letters and cards should be answered personally I feel that this is common politeness After all, the mere fact that they have written to you is a compliment, and a cold-blooded reprint without a personal note is somewhat inhuman Although of a retiring and introverted nature, on this point I am willing to take on all comers In this troubled age a return to the courtesy of more leisured times is all the more essential.

Still want me to look at your paper?

UNCLE M—.

Medicine and the Law

Effects of a Plastic Operation

ON Dec. 10, 1952, a plastic surgeon performed an operation to remove excess fat from beneath both eyelids of a 29-year-old woman outpatient Before she returned home the patient received certain directions from the surgeon, who also told her the telephone number of his consulting-rooms and arranged to remove the stitches on the sixth day The patient subsequently developed lumps below both eyes She sued the surgeon alleging, inter alia, negligence in the postoperative treatment. The allegations were denied

Mr Justice McNAIR, awarding the patient £1408 damages, said that the defendant was a well-qualified plastic surgeon, he shared with another surgeon consulting-rooms and the use of a secretary, and at this address there was a resident janitor and his wife His Lordship accepted that the surgeon, on being told that the patient could not afford his usual fee and additional nursing-home charges, had reduced the fee to 10 guineas inclusive on the basis that the operation would be done under a local anæsthetic and that she would be an outpatient No charge of professional negligence could be made against the surgeon solely on the ground that he had not insisted on retaining the patient in a nursing-home after the operation, although it was clear that this course involved some increased risk. No criticism was directed to his technique for this operation It was clear that the first 48 hours were of crucial importance as bleeding might occur and, if not attended to properly, irreversible damage might result It was on the failure to carry out sufficient aftercare that the patient's case rested

If a patient was operated on and then allowed to go home, proper directions should be given by the surgeon to the patient (as had been done in this case) and the surgeon himself, or a properly qualified substitute, should be available and accessible to deal with any untoward development until the patient's next appointment If the surgeon was relying on a telephone message from the patient to deal with an unexpected emergency it was essential that the telephone should be adequately covered in the sense that messages would be received and transmitted to the surgeon That had not been done in this case On the first day after the operation there was substantial bleeding from the stitches, which continued intermittently for a day or so Proper notification of the bleeding was communicated by telephone to the number which had been given, but such notification was not received by the surgeon His lordship held that this was due to the surgeon's failure to keep his telephone adequately covered, or the failure of those for whom he was responsible to inform him of the message That failure amounted to professional negligence

His Lordship had reached the conclusion that the condition from which the patient now suffered was directly caused by the failure to deal with the initial bleeding within the first 48 hours, and accordingly the defendant was liable

Interruption of Continuous Care and Treatment

A husband petitioned for divorce on the ground of his wife's incurable insanity The answer put forward was that the requirement that the wife must have been continuously under care and treatment for at least 5 years immediately preceding the presentation of the petition was not fulfilled

The marriage took place in 1948 In November, 1952, the wife was admitted to St. Ebba's Hospital, Epsom, as a voluntary patient, with schizophrenia She remained there until May, 1955, when she was taken to Cheam Sanatorium for treatment for tuberculosis She remained in Cheam Sanatorium for 11 weeks, and then, owing to a deterioration in her mental condition, was readmitted to St Ebba's as a voluntary patient and had remained there ever since

Mr Justice LLOYD-JONES said that to succeed, the husband must prove (i) that at the date of his petition the wife was incurably of unsound mind, and (ii) that at that date she had been continuously under care and treatment for at least the immediately preceding 5 years The first of those requirements had been proved, but a difficulty arose on the second

Under section 1 of the Matrimonial Causes Act 1950, a person of unsound mind was deemed to be under care and treatment while being treated as a voluntary patient, provided such treatment followed without any interval a period during which the patient was detained as a certified patient As the wife in this case remained throughout a voluntary patient, that requirement was clearly not fulfilled That Act, however, had been amended by the Divorce (Insanity and Desertion) Act 1958, so as to extend its operation in several important respects Thus, as a result of the 1958 Act, a person was to be deemed to be under care and treatment at any time when he was receiving treatment for mental illness "as a resident in a hospital or other institution provided, approved, licensed, registered or exempted from registration by any Minister or other authority in the United Kingdom, the Isle of Man or the Channel Islands" Again, treatment as a voluntary patient now sufficed without the necessity of a preceding period of detention under certification

Although, therefore, the husband was not confront with any difficulty arising from the fact that the wife w throughout the material period a voluntary patient onl in his Lordship's view, the phrase in the 1958 Act "re dent in a hospital provided by any Minister" m be construed to mean a hospital provided for the purpo of giving mental treatment The evidence had establish that while St Ebba's was a mental hospital, Chea Sanatorium was used solely for the reception and treatme of tuberculous patients Moreover, in connection with t wife's stay at Cheam Sanatorium, she had been required discharge herself as a voluntary patient from St Ebba's May, 1955 As a result, she ceased, for the 11 during which she was at Cheam, to be on the books of S Ebba's This distinguished the case from that of Swym v Swymer, decided in 1955, in which a husband who w a voluntary patient in a mental hospital was sent for months to another hospital for treatment for a fractur leg, but his name remained on the books of the men hospital during his absence, and it was held that that fa prevented the 5-year period from being broken H Lordship therefore held that the 5-year period in t present case had been broken for 11 weeks Although t 1958 Act provided that in determining whether any peri of care and treatment had been continuous, any interru tion of such period for 28 days or less should be d regarded, the 11 weeks' interruption was fatal T petition was therefore dismissed

Mesure v Mesure—*Probate, Divorce & Admiralty Division* Ll Jones, *J* April 1, 1960 Counsel and solicitors G H Crispin and H Figg (Culross & Co), R B Holroyd Pearce and N A Medawar (O Solicitor as guardian *ad litem* for the wife)

D R. ELLISO
Barrister at La

Abnormal and/or Depraved?

Patrick Joseph Byrne, a 29-year-old labourer, enter women's hostel, strangled a young woman, decapitated the body The victim was apparentl stranger to him

At his trial on a charge of murder, the defence asked jury for a verdict of manslaughter under the Homicide 1957, on the ground of diminished responsibility [1] T defence called a psychiatrist, who said that Byrne was abnor rather than depraved

Commenting on the medical evidence, Mr Justice S said he could not see why a man could not be abnorm depraved "There is a distinction between the two but does the one necessarily exclude the other?" His Lor went on to say that he would give the jury a direction which, if it was wrong, would be corrected by the Co Criminal Appeal The relevant section of the Homicid was, he said, new in English law "It is a mercy se intended for the protection, for the alleviation, of a man has done a criminal act whose condition does not bring within the McNaughten rules, but who mentally is not q as other men are"

The jury would consider whether the object of the se was to provide some additional protection to the utterly vic or whether the object was to provide some protection for mentally afflicted "If the legislature had intended th man who strangles a woman under the *influence* of whelming violent and perverted lust should be immune the ordinary consequences of his act it would be so sim pass an Act of Parliament in those terms They have not so If there is evidence which leads you to say this man is *responsible, as other men are, for the full consequences* of he did—if there is nothing else then I say the vicious, dep tendencies, thoughts, desires, lusts and conduct do not b the accused within the section and that does not cons ch abnormality of mind as substantially to impair his mental responsibility for his acts"

---

[1] *Times*, March 25, 1960

The jury returned a verdict of guilty of murder, and—since the offence did not constitute capital murder—Byrne was sentenced to life imprisonment

It is understood that Byrne has appealed to the Court Criminal Appeal, and comment on Mr Justice Stable's summing up must await the outcome of that appeal

Symposium

FORMATION AND BREAKDOWN OF HÆMOGLOBIN

A SYMPOSIUM on this subject was held at the meeting of the Association of Clinical Biochemists, in conjunction with the Biochemical Society, at Leeds on March 26 Dr C P STEWART and Prof G H. LATHE presided

Iron Incorporation in Hæm Biosynthesis

A. GOLDBERG (Glasgow) said that an in-vitro method had been established by means of radioiron (^{59}Fe) whereby the enzymic incorporation of iron into protoporphyrin, an intermediate in hæm biosynthesis, could be accurately measured. An aqueous "particle-free" extract of chicken erythrocytes contained an iron-incorporating enzyme (I.I.E.) This extract could be separated by ultrafiltration into two fractions, a residue which contained the enzyme and an ultrafiltrate which markedly potentiated the action of the enzyme The ultrafiltrate contained dehydroascorbic acid, glutathione, and ergothioneine in concentrations of the same order as were found in human erythrocytes and in these concentrations each of them potentiated the effect of the enzyme Homogenates of human and rat liver, kidney, and spleen, and of human bone-marrow and reticulocytes were also sources of I.I.E. A spleen which showed histological evidence of extramedullary erythropoiesis had an enzymic activity nearly four times greater than that of one without. Dialysis of these tissue homogenates against water led to a marked loss of activity as well as a considerable reduction in their contents of ascorbic acid and glutathione (G.S.H) Enzyme activity was restored on addition of ascorbic acid or G.S.H to the dialysed extract. Of the intracellular components of human and rat liver the mitochondria were the richest sources of I.I.E.—a link with the finding of Bessis and ton-Gorius that ferritin iron is mainly concentrated in the chondria of the hæmoglobin-forming erythroblast. The mic activity of the mitochondria was also potentiated by addition of ascorbic acid and G.S.H Further studies had n that these physiological reducing substances rendered in-bound iron available for hæm biosynthesis Radioiron incorporated into rat plasma and liver and human serum e radioactivity was shown to reside in the β-globulin gesting the radioiron was attached to siderophilin Ascorbic d and G.S.H. facilitated the transfer of radioiron from human rat siderophilin and also from rat-liver homogenate for its enzymic incorporation into protoporphyrin, the concentrations ch did so being within the ranges of those which occur in man as well as rat liver Thus these substances played a t in the transfer as well as the utilisation of iron

ole of Conjugation in the Excretion of Bilirubin

BARBARA H BILLING (London) said that excretion of bilin in the bile or urine was only possible if it was first erted to a water-soluble derivative. In mammals the most important conjugates seemed to be the ester glucuronides, phate was also formed and there was evidence for small antities of other unidentified conjugates Conjugation took ace in the liver microsomes as the result of the enzymatic n of a glucuronyl transferase with uridine diphosphate ucuronic acid (U.D.P G.A.) acting as the glucuronyl donor Extrahepatic conjugation had been demonstrated in vitro and in hepatectomised animals but it was not known if this was important in normal subjects The capacity of the liver for conjugating bilirubin in adults was considerably greater than that normally required for the excretion of the breakdown products of hæmoglobin In hæmolytic disease, however, this may be exceeded so that mild jaundice occurred Impairment in the conjugation of bilirubin resulted in its accumulation in the body so that both tissues and plasma became icteric. This may be due to a deficiency of glucuronyl transferase such as was found in the newborn and was responsible for the development of "physiological jaundice" This enzymic defect was also found in patients with the severe type of hyperbilirubinæmia first described by Criggler and Najjer and in Gunn rats In mild forms of congenital hyperbilirubinæmia (Gilbert's disease) the raised serum-bilirubin levels could not be explained by an enzyme deficiency and a more likely explanation was a reduced hepatic uptake of bilirubin from the plasma Although conjugation was essential for the secretion of bilirubin by the hepatic cell, it was not necessarily the limiting factor In the Dubin and Johnson, and Rotor types of familial hyperbilirubinæmia, in which there was no evidence of intrahepatic or extrahepatic obstruction, both conjugated and unconjugated bilirubin accumulated in the plasma. There therefore appeared to be a specific defect in the secretion of conjugated bilirubin the mechanism of which was not known In the newborn this mechanism may be slow to develop since in a few families, who had received exchange transfusions as treatment for erythroblastosis, it had been observed that, during the recovery period, conjugated hyperbilirubinæmia developed. At present little was known of the mechanism of excretion of conjugated bilirubin by the kidney Tubular secretion had been demonstrated, extremely low clearance figures were obtained in hepatitis and obstructive jaundice and these varied considerably during the course of the disease.

Effect of Icterogenin on Biliary Secretion

C. RIMINGTON, T HEIKEL. B C. KNIGHT, E. J WILLIAMS, and H D RITCHIE recalled that in 1937 Rimington and his coworkers studied a disease in South African sheep which was characterised by icterus and photosensitisation phenomena. They showed the disease could be reproduced by the administration of extracts from the plant *Lippia rehmanni* The active agent was isolated and found to be a triterpene acid, which they called icterogenin This inhibited bilirubin excretion in some animals, without concomitant evidence of toxic liver damage It was thought a closer understanding of the mechanism whereby icterogenin produced this effect might help to illuminate some cases of human jaundice. The rabbit was found to be the only suitable experimental animal Biliary fistulæ were created by cannulating the common bileduct and ligating the cystic duct, and the toxic agent was introduced into the peritoneal cavity The technique used produced regularly a colourless bile within 8–24 hours, usually followed by recovery over the next 2–3 days In a rabbit dosed with icterogenin, bile volume was much diminished, bilirubin, bromsulphalein, coproporphyrin, and phylloerythrin excretion were suppressed during the stage of action of the drug, excretion of them then slowly returning Alkaline-phosphatase excretion was affected to a much smaller extent, if at all, and bile salts were present in significant amount. Histological examination revealed no distinct abnormality Reverse-phase chromatography of the pigments in the serum of the dosed rabbits showed an accumulation of pigment I The possibility that icterogenin suppressed bilirubin and bromsulphalein excretion merely by interfering with conjugation may be rejected, firstly, since different conjugates were involved bilirubin with glucuronic acid and bromsulphalein with aminoacids and secondly, since rabbit bile, rich in bilirubin diglucuronide, when injected intravenously, was not excreted by the icterogenin-poisoned animal. Reviewing all the experimental findings, a possible hypothesis might be that mild intoxication with icterogenin caused a slowing of the passage of the test substance through the liver cell Higher doses may temporarily inhibit biliary excretion, probably owing to altered permeability of the cell membrane facing the bile canaliculus Bile accumulated in the liver cell and may be segregated in vacuoles or it may ultimately flood the cell and pass through the cell membrane into the sinusoids These changes do not produce histological findings visible by conventional techniques

The Urobilins

D NICHOLSON (London) said that the urobilins and their colourless dihydro derivatives are the ultimate products of biological reduction of bilirubin glucuronide Only *i*-urobilin has a structure fully established by degradation and synthesis, it is usually formulated as *bis*-hydroxypyrrole Until 1958 only two other members of this class of pigment were known—stercobilin and *d*-urobilin, shown to be tetrahydro and dihydro derivatives respectively of *i*-urobilin So-called "hydroxypyrroles" have been shown to exist in a pyrrolenone form and bile pigments in general may be assumed to have *bis*-pyrrolenone structures A *bis*-pyrrolidone structure for stercobilin has been established Some progress towards elucidation of the structure of *d*-urobilin has been made, and these studies suggest that the pigment differs from *i*-urobilin by containing a centre of unsaturation attached to, or in, one ring From tetrahydro-*d*-urobilin a new *d*-rotatory isomer of *i*-urobilin (*d*-urobilin-IX α) has been obtained On classical views, tetrapyrrolic *bis*-hydroxypyrrole compounds would not be expected to show optical activity, the existence of *d*-urobilin-IX α was therefore considered additional evidence for a *bis*-pyrrolenone structure for *i*-urobilin Optical rotatory dispersion studies suggested, however, that asymmetric carbon atoms were not the sole source of optical activity in these pigments Comparison of oxidation products of *i*-urobilin with those of *d*-urobilin and its derivatives indicated the possible existence of geometrical isomerism in these compounds Recent theoretical studies revealed a higher electron density at the α-methene group of protoporphyrin IX than at the other three methene groups Protoporphyrin may therefore be expected to undergo fission preferentially at the α position and all natural bile pigments should have the "IX α" order of β side chains exclusively, this had been confirmed by degradation of the pigments to pyrrolic acids

---

Public Health

Statistics for 1959

England and Wales

Provisional figures issued by the Registrar General[1] show that last year the death-rate from all forms of tuberculosis was 85 (respiratory 77) per 1,000,000 population. The death-rate from cancer of the lung and bronchus in men was 831 per 1,000,000 population (784 in 1958) and in women 123 (119 in 1958) In males deaths from this cause accounted for over 35% of all deaths from cancer, in women this proportion was just over 6% The provisional maternal mortality-rate was 0 38 per 1000 live and still births (0 43 in 1958) and the neonatal mortality-rate was 15 8 per 1000 live births (16 2 in 1958)

Eire

In Eire last year the death-rate was 12 0 per 1000 population, which was the same in 1958[2] The death-rate from all forms of tuberculosis was 0 18 per 1000 population The maternal mortality-rate was 0 66 per 1000 births registered, compared with 1 03 in 1958, the infant-mortality rate was 32 per 1000 births registered (35 in 1958) and the neonatal death-rate was 21 (23 in 1958)

Census of Population

The date of the next Census in Great Britain is Sunday, April 23, 1961

In England Now

A Running Commentary by Peripatetic Correspondents

"WHEN I borrow money from you," said Ananias plaintively, "you might at least provide new banknotes This one resembles in all but value a dilapidated Dead Sea scroll I ask you to believe that my interest in 'crinkle' is purely æsthetic, like that of my cousin Fred who for several months provided a valuable public service as a peripatetic bureau-de-change outside Victoria station

"In exchange for their native currency, unwary travellers received neatly wrapped bundles of used London Passenger Transport tickets, under the impression that they were a new issue of English banknotes Fred put it very beautifully when he said that the rapacity with which some people plunged into such black-market currency dealings filled him with a sadness that resembled sorrow as the mist resembles the rain It was probably because of the mist that he failed to see a policeman coming and felt in consequence compelled to change his business address for one in a less damp climate

"Unluckily his collection of tickets did not include one for the boat, which he was persuaded to leave in Barcelona, or for the bull-fight which he was compelled to leave in Madrid Furthermore, the manager, who must have kept a diary, remembered being a customer of Fred's at Victoria, and was so uncharitable in his attitude to Fred's story about searching all over Spain to give him his money back that Fred climbed over the wrong wall and found himself in the bull-ring His appearance caused some confusion, during which two bulls got loose at once and charged him from the N.E and S W simultaneously Fred achieved a last-minute vertical take-off that would have gladdened all hearts at Cape Canaveral, and the two animals collided and knocked each other unconscious

"The novelty of this spectacle appealed to the audience as much as its economy appealed to the manager, who realised that the bulls—and if he was nippy enough, Fred—could be used next time, and sooner than disappoint his (the manager's) public, decided that Fred would perform every evening at seven, matinees Tuesdays and Saturdays

"After a time, however, the bulls must have started comparing notes, and although they never understood the situation, they decided that if a matador was so unsporting as to fill his hip-pocket with flat-irons, they wanted nothing further to do with him, and Fred received notice in lieu of a week's salary He had the best of the bargain as he wasn't being paid anyway, but what with keeping his eye on the bull—or rather on two bulls—he developed bull-fighter's nystagmus and was run out of town by indignant Spaniards who thought he was ogling their women-folk

"A firm of travel-agents called INTERPOL arranged his passage home and a period of two years' convalescence Unhappily it was of no use, because soon after he came out Fred died of overwork He had been in partnership with a man who made model ships in bottles, and it was Fred's job to empty the bottles"

• • •

It is impossible to foresee what the world will be like in the year 9000, but harmless to speculate Despite the 350 world wars which are statistically predictable and which *will have* helped to reduce world population by that time, the population of Australia alone will then stand at about 400 million people Let us suppose that in the *third millennium* an error in the calculation of the trajectory of an atomic missile, caused by metal fatigue of an electronic brain, exposed the whole eastern seaboard of Australia to sublethal irradiation As so often in the course of history, this seeming catastrophe proved to be a blessing in a country whose chief source of food had now become the sea

This unplanned irradiation produced a number of favourable as well as unfavourable mutations One of the more favourable was that in a certain number of people the proerythroblasts lost their ability to distinguish between the metals, iron and magnesium, which ability had hitherto been essential to the synthesis of hæmoglobin. Nevertheless, the fortunate possessors of these unique proerythroblasts developed a bone-marrow which produced not only white cells and red cells but also green cells The chlorocytes, when activated by the sun's rays, were capable of synthesising carbohydrate Thus the simple expedient of exposing the body to the sun's rays on Bondi Beach became a method of sustaining life, and one to which the Australian population was peculiarly adapted

Undesirable animal mutants occurred, such as meat-eating cattle, but some sheep and cattle were bred which had also a quota of chlorocytes in their bloodstreams These animals no longer required grass, but, with a plentiful supply of sunshine and water, were able to manufacture their own foodstuffs The cattle and sheep were kept in paddocks paved with green concrete, since sentiment is a powerful emotion. When left alone, the cattle grew and fattened without any great attention except for an occasional spraying in order to keep off the green aphids

The world became an easier place to live in, except for one small thing Many people and animals developed psychoneuroses, since they were deprived of the one function in which they had most delighted to indulge—eating

I was very pleased to get an office at all when I moved into the new unit, but I did not expect to have to share it with a ghost. For the first few days I did not realise that it was haunted, but when I decided to make some improvements the trouble started. I began by negotiating with the secretary for a clean piece of blotting-paper It shone splendidly on my desk for a day, but when I came in next morning the blotting-paper was decorated with a lively drawing of the head of a devil, boldly executed in my black ink. I turned the paper over, since hospital policy does not allow me a clean piece of blotting-paper more than once a week.

My next attempt to improve the amenities was to ask Sister for a second armchair The one already present was on the patient's side of my desk, and I saw no reason why I too should not relax during interviews My ghost thought otherwise. Next day the chair had vanished I reclaimed it from the lounge and pinned a notice to it "Please do not remove this chair" The chair has remained, so I assume that my ghost is literate It seems indeed to be not only literate but educated, since in my desk drawer yesterday I found a copy of Plutarch's *Essays* This would not have been my first choice for passing the time, as I prefer Marcus Aurelius, but it shows a commendable breadth of interest. Today I intend to leave out a note with "1 P-K4" on it, to see what happens

SALT RETENTION

Dear, do not weep—
Since recent years
It is more wise to keep
A watch on tears

Some seek to analyse
With callow art
An easy pathway from your eyes
Into your heart

While others feel
That tears are nothing fine
And have no power to heal
More strong than lysozyme

Besides, you should not grieve
But keep your sorrows pent—
There's not a man can quite forgive
Embarrassment.

Letters to the Editor

PLACENTA PRÆVIA

SIR,—Since 1947 not more than 30 and not less than 20 cases of placenta prævia have occurred in any one year in Bradford, so that the fœtal wastage from this condition is negligible compared with that from antepartum hæmorrhage sine P P I am, therefore, in complete agreement with Professor Macafee's views and share his high esteem for Dr Blair Hartley's outstanding contribution to obstetric radiology

I have ventured to enter this almost private controversy because it seemed to me that Dr Blair Hartley, in his letter of April 9, inferred that maternal lives might have been lost because either the patients themselves or their doctors were afraid to avail themselves of radiological investigations

We used to do X-ray pelvimetry on over 300 patients each year, together with a goodly number of placentograms Some three years ago my colleagues, Mr G A. Craig and Mr A. C Muir, and I decided (*a*) to stop mass radiography of the chest in antenatal patients and to substitute careful filming (and to stop even this procedure if the results failed to warrant it), (*b*) to stop X-ray pelvimetry and placentography, and (*c*) to limit the use of X-rays to confirming (or not) the diagnosis of fœtal abnormality, and of multiple pregnancy, and to determining the fœtal presentation in doubtful cases

During the past nineteen months there have been over 8500 deliveries in the city of Bradford without a single maternal death, and it cannot, therefore, be argued that the abandoning of X-ray pelvimetry and of placentography has caused maternal loss of life Neither do we think that any infant has been lost because of the above decision

Dr Blair Hartley admits that X-ray investigations may involve a slight risk to the fœtus, everybody is agreed that ionising radiations should be limited to the absolutely necessary level, and, it is suggested, the Bradford limitation on the clinical reasons for inviting examination by the X-ray method has not resulted in either maternal or fœtal loss of life, or an increase in the cæsarean-section rate.

Bradford. G W THEOBALD

FLUORIDATION

SIR,—Dr Dobbs (April 2) makes some statements which call for challenge One is that there can be no direct evidence on the toxic effects of pollution unless experimentation is carried out on an impossibly massive scale. The context of the discussion is water, and solely for the purpose of the argument the view that fluoride is a pollution will not be here contested, it is pertinent, then, to point out that Nature has herself carried out the experiment which Dr Dobbs considers impossible and that a mass of studies attest to the fact that use has been made of this Again, Dr Dobbs holds it as "mere speculation" that there is a critical level below which the fluoride ion loses its toxic character and becomes physiologically beneficial Several other elements have a beneficial effect at low level and a toxic effect at high level—e g, iron

Does Dr Dobbs propose that every drinking-water in the country should have its fluoride content removed, and if not, why not? Also, in his keenness to avoid an intake of this toxic substance does he avoid eating chicken at 1 4 p p.m, liver at 1 5 p p.m., lamb at 1 2, canned fish at approximately 4 or more, and honey at 1 0 part per million? Presumably he also avoids drinking tea, which is quite a good source of fluoride too Deprived of drinking tea he cannot turn to beer with confidence as this may contain approximately 1 p p m of fluoride!

Discussions of fluoridation do not always centre on the dental aspects to the exclusion of a potential health hazard At the Royal Society of Health Congress in May, 1957, there was a symposium on fluoridation and papers by Dr W Alcock and Dr W T C Berry which discussed public-health and toxicological aspects Few if any papers on this subject by proponents fail to discuss the safety aspects

When we learn from such a high authority as Prof Hugo Theorell that " fluoride ion can inhibit lipase at 1 part in five million " we wonder why it is that the inhabitants of West Mersea, for example, where the water contains many times this concentration (5 8 p p m , compared with the more common 0 2 p p.m) are not all in hospital with steatorrhœa Could it be merely that Professor Theorell's observation relates to in-vitro study, and that the in-vivo picture is quite different?

Public Health Department,
Bradford

C L SHARP

SIR,—Dr Dobbs is surely not on very firm ground in questioning the possibility of fluoride, though toxic in larger doses, being beneficial at lower levels of intake Nor is he any more justified in claiming dental fluorosis, perhaps an unfortunate description, as necessarily a toxic manifestation

Fluorine is invariably present to some extent in human enamel and in that context all human enamel can quite fairly be described as fluorosed Where the drinking-water contains 1 p p m F, the fluoride content of the enamel is higher, the enamel is better in quality and, in addition to being more resistant to decay, contains fewer developmental defects [1,2] This can be seen in the Slough, Bucks, natural-fluoride area (0 9 p p m) where no-one who has had the privilege of examining the children's teeth could fail to be impressed by the splendid quality of the dental enamel and in particular that of the incisors Their beautiful colour and obvious high resistance to decay was to me little short of amazing Clinical judgment, quite apart from any statistical evaluation, was sufficient to carry complete conviction

Whether fluorine is in fact an essential trace element may be open to question, but Roholm [3] did call attention to evidence that fluorine was necessary for the maturation of rye, and other experiments have claimed to show reduced fertility in rats fed on a fluoride-free diet Dr W T C Berry,[4] writing of the improved quality of dental enamel conferred by moderate amounts of fluoride, could not recall any similar improvement in well-being, brought about by the consumption of an element, in which that element had not been shown to be essential

Exeter

JEFFREY FLETCHER

HYPERBILIRUBINÆMIA IN PREMATURE INFANTS

SIR,—In the paper by Dr Corner and her colleagues (April 2) it is stated that " Clinically, synkavit and 'Sulfasoxazole' have also been associated with hyperbilirubinæmia, and the inference is that these drugs interfere with bilirubin conjugation "

The role of synkavit in the production of neonatal hyperbilirubinæmia is not in dispute although the mechanism is not entirely clear However it would be of interest to know what evidence, clinical or otherwise, implicates the sulphonamides in the production of hyperbilirubinæmia or interference with bilirubin conjugation

The cases of kernicterus in newborn infants receiving sulphonamides were not associated with supranormal levels of serum-bilirubin [5] The kernicterogenic property of the sulphonamides is due to displacement of bilirubin from the bilirubin-albumen complex in the blood [6] and possibly to an alteration in the permeability of the blood-brain barrier [7]

It is of critical importance to realise that newborn infants on sulphonamides may get kernicterus at blood levels of bilirubin believed to be harmless and that intense jaundice is not to be expected

THOMAS E OPPÉ

AN EASIER ALPHABET

SIR,—May I thank Dr Thomas for his kind remarks (April 9) and interesting discussion on redundancy?

As speech has developed through the ages 50% redundancy may represent a compromise between the speaker's haste and the recipient's incompetence If 50% is adequate for speech there is no need for 2500% in our written language, especially as the rate of information intake is entirely under control of the reader Illiterate people could be helped by increasing redundancy only if the extra information increased the differences between the letters, and even then it is doubtful One could design an alphabet in which every letter differed from its fellow by two, three, or more units of information, but at each step the letters become more complex. An illiterate might find them more difficult, rather than easier, although the differences were greater Roman numerals have a higher redundancy than Arabic yet illiterates do not find them easier—in fact, the easier Arabic, which were introduced some six hundred years ago, have almost replaced the more difficult Roman If an object has many characteristic features it is usually identified by the most conspicuous and there the process ends There is little point in examining the object again and reidentifying it by a second feature, much less a third or fourth unit of information

To increase redundancy without increasing the differences between letters, by adding curls, balls, and spikes to every letter delays the writer, confuses the reader, and helps no-one This is the useless type of redundancy present in our written language which makes illiterates out of many who can talk fluently and understand the spoken word without difficulty

Whittingham Hospital,
Goosnargh, near Preston

S L PUGMIRE

SIR,—The word " redundancy " when applied to written language can have at least two quite distinct meanings When Dr Thomas says that " it is an accepted principle of communication theory that redundancy serves to protect against errors in transmission " this is true only of redundancy in the design of the signal units, in this case the individual letters of the alphabet For instance, the letter y must have a tail to distinguish it from the letter v, and though a tail three times as long might be thought redundant it would certainly make distinction that much easier, and consequently reduce any " errors in transmission " between page and perception

In practice the degree of redundancy in letter design affects efficiency of communication much less than does redundancy in the *use* of letters To use the letters ugh to represent the sound f in the word " cough " cannot by any stretch of logic or imagination be said to " protect against errors in transmission " It is this form of redundancy with which Dr Pugmire is chiefly concerned, and his experiments with coloured cards of different shapes show that the inclusion of irrelevant information only makes reception of the message more difficult

When Dr Thomas says that a case might be made out for designing a language with high redundancy this could only be so if illiterates' difficulty lay in distinguishing individual letters The inclusion of redundant letters could no more improve recognition of written symbols than could a compact

[illegible] cause the increase in illiteracy which Dr Thomas fears To write " committee " instead of " comity " helps no-one—not even that stupid listener to whom one has to say the same thing over and over again

Lee-on-Solent A. S JARRETT

THE MEDICAL SERVICE COMMITTEES

SIR,—The tragic thing about the disciplinary tribunals is that they need to exist at all However, what are a family to do when they discover their G P is lazy and incompetent? At first they will decide to change their doctor Having found their E C 4, they see they need to obtain the consent of the doctor they wish to leave in order to transfer They may not wish to do this, for obvious reasons If they do not wish to move house, the only alternative is for them to write to the executive council, who will effect a transfer after 14 days

In the meantime granny is dying of pneumonia, and in desperation a relative calls on Dr D down the road Naturally, he feels diffident about accepting a colleague's patient under the circumstances, and this innocent feeling may be misinterpreted by the relative who thinks the local doctors are ganging up against him In a fit of pique he lodges a complaint

Those of us who want the capitation system abandoned have always recognised this muddle as one of its greatest faults Capitation medicine must necessarily be static—doctors having " lists ", and patients " belonging ", sometimes to their detriment. Dr Wheatley (April 16) should actively support some more competitive and efficient system of medicine instead of trying to get at the executive council Unfortunately your solution, Sir, is no better How can an advocate protect his client when hearsay is admitted, and the rules of evidence are ignored? How can a chairman exercise proper control if procedure may be arbitrary?

Worthing RICHARD H DAVISON

PALLIATION IN MALIGNANT STRICTURE OF THE ŒSOPHAGUS

SIR,—Mr Moghissi's article (March 26), recommending the use of the Mousseau-Barbin tube in the palliation of œsophageal stricture, prompts us to report our less fortunate experience in two recent cases

Our first patient was a woman of 75, admitted with almost total dysphagia from an inoperable carcinoma of the lower third of the œsophagus A Mousseau-Barbin tube was inserted, but it became dislodged upwards during the first 24 hours by postoperative vomiting so that its lower end lay embedded in tumour tissue. Dysphagia was not relieved and the patient died 3 weeks later At postmortem examination, the expanded bell of the tube was found to have produced a deep annular pressure ulcer, which had eroded through the œsophagus producing a deep groove on the aorta It was apparent that had she survived a few weeks longer, the aorta would also have been penetrated.

The second patient was a man of 82 with a simple stricture of the lower œsophagus When the stricture could no longer be dilated with œsophageal bougies, a Souttar's tube was inserted at open operation, and gave complete and painless relief for a period of 3 months, at this time the tube slipped through the stricture, and dysphagia soon recurred A Mousseau-Barbin tube was inserted, and although the patient's dysphagia was relieved he complained of persistent severe pain girdling the lower chest from the early postoperative period until his sudden death from hæmorrhage 22 weeks later Postmortem examination showed that the bell of the tube had eroded not only the œsophagus but also the aorta, producing the terminal catastrophic hæmorrhage. In addition, the lower end of the tube had produced a deep ulcer of the lesser curvature of the stomach

The Mousseau-Barbin tube has the great advantage of relative ease of insertion, but our very limited experience suggests that the present design in 'Neoplex' is too rigid for safety, and would be better replaced by a more resilient material, better able to absorb the repeated trauma of aortic pulsations

LUNG CANCER AND TOBACCO MOSAIC VIRUS

SIR,—I am glad to note that in his comment (March 26) on my letter, Mr Pirie acknowledges the need for investigation of the possible relationship between tobacco mosaic virus (T M V) and lung cancer and that he has gone so far as to suggest a way in which this may be done

His analogy of the effect of a temperature gradient on the cellular R.N.A of grilled steak does not appear to be relevant, unless he considers that all R.N.A.s are equal, in spite of the generally held view that some must be more equal than others! Surely the specificity of large molecules [1] does imply considerable differences between the R.N A.s from various species, and surely it is the code carried by these molecules which is important rather than the presence of entirely different components in some R.N.A s compared with others Mr Pirie has put this matter as clearly as anyone " We do not know how similar the component parts of a virus are to normal components of the host, they may even be identical but differently arranged " [2]

His analogy of grilled steak is in fact somewhat unfortunate and it would have been more appropriate to compare the effect of heat on frying tomatoes, as these might at least contain a plant-viral nucleic acid which might well be T.M V R.N.A It would also have the advantage that fried foods have been associated with the production of gastric cancer [3] However, as it is most unlikely that either the steak or the tomatoes would be cooked in tobacco, the uniqueness of the temperature gradient and the processes surrounding it remains a fact for T M V (and other plant viruses) in the cigarette.

The two a-priori requirements which Mr Pirie cites are volatility for the nucleic acid and a special component in the R.N.A of T.M V which is not found in other kinds of R.N.A. So far as volatility is concerned, I referred to the difficulty of seeing how the whole virus could pass over in tobacco smoke in view of its high molecular weight If, however, ingestion rather than inhalation is important, then the question of volatility does not apply Additionally, it would be necessary to consider whether nucleotides and nucleotide complexes derived from the R N.A. might not in fact be carried over in the smoke. Neither does the a-priori postulation of a special component in the R.N.A of T.M V appear to be required The specificity of nucleic-acid molecules is not due to their possession of special components but almost certainly to the way in which these components are arranged and to the information code which they thereby convey Small differences between normal and abnormal hæmoglobin [4] accentuate how small these changes may be to have wide implications, and the present conception of D N.A as a transmitter of hereditary information would be invalid without them The conditions which surround viral R.N.A. near the burning end of the cigarette provide conditions in which analogue substitution can readily be envisaged in the R N.A or in its nucleotides Also according to Reddi [5] the composition of T.M V R.N.A. is in fact different from the R.N.A. in the healthy leaf in that the uracil content of the virus was

found to be about twice that in the plant R N A , so that there is also a difference here, contrary to Mr Pirie's view

It is possible that the products of combustion of tobacco contained in tobacco smoke could pave the way for other carcinogenic agents, exogenous or endogenous The evidence relating to the evocatory effects of nucleic acids and their breakdown products [6] should constitute reasonable grounds for investigating the role of the viral T M V nucleic acid Since so little is really known about the effect of cocarcinogens and other substances on the structure of R N A and since even less would appear to be known about the relationship of R N A to neoplasia, work to exclude a possible relationship is desirable

Opinions about improbability and the postulation of a-priori requirements are highly unsafe in a field where so much is unknown One investigation would be better than a thousand opinions and comments

P W BOTHWELL

CORPORAL PUNISHMENT

SIR,—Although apparently shocked by Dr Waycott's statement (March 26) that there is no proof of the deterrent effect of corporal punishment, Dr Webster (April 2) gives no fact more relevant than the work of Pavlov

The waters of psychology are deep and treacherous, but there are one or two points worth consideration The "teddy-boy" outlook includes a masochistic element, seen in the curious attitude to the carcinogenic aspects of smoking the smoker is now a hero facing martyrdom, looked on with awe by his schoolfellows Likewise the birched boy became a hero

More disturbing still is the undoubted connection between corporal punishment and sexual stimulation the Marquis de Sade was not altogether a fraud Dr Webster might do worse than read certain passages in *Mr Norris Changes Trains* or *Brave New World*

Birmingham

ROBERT J HETHERINGTON

IRON-DEFICIENCY ANÆMIA IN THE TROPICS

SIR,—Your issue of Nov 14, passed on to me by a friend, is just to hand in the interior of the Bornean jungle You comment (p 831) on the W H O report on the anæmia which is such a problem in the tropics

While I agree that vitamin B_{12}, &c , is not necessary and that ferrous sulphate works wonders, I would suggest we should simplify the therapy In my experience it is definitely better to avoid using "pills", for, of course, this leads to thousands of sufferers with a continual dependence on "pills" and more particularly the middle man who seldom hesitates to exploit his "wonder-working wares" amongst the poor interior peoples whom we doctors may have encouraged into this dependence

In one community of North Borneo Muruts with whom I lived I found a striking anæmia in a high proportion of the people and a very severe anæmia in many of the women By insisting on the eating of vegetables three times a day and drawing the whole community's attention to the situation we were able to transform the position The long-term result has meant the virtual elimination of anæmia without a single pill being consumed The community is also serving as an example to others who have no hope of meeting a doctor in the remoteness of the Bornean jungle

Besides the usual ætiological factors in the sex-distribution there is an additional local factor In animism as practised by the Muruts there are severe taboos on the eating of green vegetables by pregnant and lactating women—thus in a community where lactation goes on for years rather than months, and where vegetables are normally only eaten when no fish meat is available from the jungle

Thus the problem is much greater than dietetics Only the who have not lived with animism would ever belittle its fa tastic power The doctor who can introduce the tribesmen a more powerful Person (*Luke*, 11, 20–22) is able to make particular contribution

Looking back home from our experience in Borne it would seem that perhaps we spend too much tin thinking of iron preparations and the relative frequenc of the gastrointestinal disturbances when we should b thinking of diet

CHILDREN IN POINTED SHOES

SIR,—Mr Thomas' reference (April 2) to an article o Chinese feet in Hong Kong could, perhaps, be amplifie

In China proper, in the immediate post-war years, th professional classes alone wore leather shoes, possibly o Japanese origin, and one and all showed evidence of hallu valgus The shoes were round-toed, low-heeled lacing shoes o relatively broad width, with a toecap, identical for men an women Most coolie women over the age of thirty had boun feet, immediately identifiable in their blue or black cotton shoe because of their tiny, pointed wedge-shape coming sharply u into the "instep" with, obviously, no use of the toes or tars joints, including the subastragaloid, and no flexion or extensio at the ankle They stumped about as if on stilts and were terr fying in traffic as they plunged into it head down and scuttle across the street, looking neither to left nor right, arriving mor often than one would have thought humanly possible

Only once in the course of wide cross-country travels an examining large numbers of women and children was I able t get a bound foot exposed Chinese colleagues had not though this possible, but I managed it under the plea of examining afte treatment for scabies, in which one insisted all the famil sharing a bed should be treated with the affected children In this instance the entire foot was turned under so that the woman walked on some part of the dorsum and somewhere underneath there was a clutter of toes covered in callosities It was an obscene sight, but the patient regarded me indifferently as I looked at it I have one X-ray of another bound foot, again obtained with difficulty through an orthopædic department it was at that time a rare possession The evidences round one showed clearly the amount of contortion infant bones will stand and explained in some part, for me, the lack of pain in toddlers' feet pushed into shoes much smaller than their feet, which used to be common enough in this country

The footwear of the younger Chinese peasant or coolie woman and of many men in towns was the reasonably shaped, often home-made stuff shoe, but everywhere one also saw men barefoot or in sandals The latter, made of straw, were constantly seen discarded—singly—on country paths and city pavements alike, as if it were too much trouble in passing to pick up a dropped shoe These sometimes had pointed fronts barely covering the toes, sometimes a thong between first and second toes The bare Chinese foot had a free hallux whose work could be well seen in the rickshaw-runner I never, repeat never, saw hallux valgus in these people I sometimes saw an enlarged first metatarsal head, for obvious reasons The coolies dragging lorries (there were practically no motor engines) or carrying loads across their shoulders frequently bore enormous weights One could quite often see a lad delivering ten wooden suitcases, slung five deep at either end of his shoulder pole, in a shopping area wardrobes or pairs of chests-of-drawers on a man's back were common Children I examined round the age of seven or eight frequently exhibited markedly pronated f with knock-knee, features not met with in the younger age groups I attributed this to their starting to carry coal or nightsoil, again in buckets slung doubly from their shoulder poles, at this tender age a male colleague tried in vain to lift by hand what one girl-child hitched on to her shoulder without too much difficulty No age, once the child had walked (they walked very late), was too young to work in China

---

[6] Davidson, J N The Biochemistry of the Nucleic Acids, p 214 London,

An extraordinary thing was the unwillingness of the very young of either sex to bare their feet (in towns they mostly wore the stuff shoe) They stripped willingly and almost uninvited as their turn approached for medical examination and let one pummel and sound them, look at their throats, and evert their eyelids (looking for the ubiquitous trachoma) without the slightest qualm, but hesitated and silently resisted till the last ditch when asked to remove their shoes Little babies often had the gayest tigers embroidered on their shoe-soles did their elder brothers and sisters think of evil spirits approaching through the foot-soles too ?

London, S W 1 MARGARET EMSLIE

TREATMENT OF FÆCAL INCONTINENCE

SIR,—Fæcal incontinence is a common and difficult condition in geriatric practice There are two main causes fæcal impaction, when the hardened rounded scybala act both as an irritant and a ball-valve allowing only fluid fæces to pass, and impaired nervous control of the defæcation reflex, due to cerebral arteriosclerosis or brain damage due to cerebrovascular accidents The patient with hemiparesis often regains the ability to walk, but tends to remain in hospital because of the difficulties of home care of an incontinent patient

Recently we have been treating these patients with neurogenic incompetence by imposing periodicity of bowel action by alternate use of agents with opposite pharmacological effects, in this case mist kaolin et morph and standardised senna (' Senokot ') given at 12-hourly intervals

The opiate, by interfering with the propulsive movements of the small and large intestines, leads to more complete absorption of water from the fæces and at the same time the tone of the external sphincter is greatly enhanced.[1] The active glycosides of senokot, on the other hand, are absorbed from the small intestine, re-excreted in the colon, and after activation by bacterial flora they stimulate the parasympathetic nerves of Auerbach's plexus This results in the reproduction of the physiological process of defæcation without any evidence of irritation of the bowel mucosa [2] By regulating the dose of the opiate mixture and the senokot, control over bowel action can be achieved. The results have been encouraging, as the following show

CASE 1—A woman of 74 Since a left hemiparesis in April, 1959, she remained in hospital, chiefly because of continued fæcal incontinence Mist kaolin et morph 15 ml o.m and senokot tabs 1 o.n were started in August, with complete control of the incontinence She was discharged from hospital in October, 1959, and has remained well since

CASE 2—A woman of 86 Already suffering from advanced cerebral arteriosclerosis, she was admitted in April, 1959, with a fractured neck of femur During her three-month stay in the orthopædic ward she was continuously incontinent of fæces Since starting mist kaolin et morph 15 ml o m and senokot tabs 1 o n in July she has remained continent

CASE 3—A man of 71 He was admitted after a severe right hemiplegia with total aphasia and double incontinence Two weeks after admission mist kaolin et morph 15 ml o m and senokot tabs 2 o.n were started and he remained continent until his death from pulmonary embolism three months later

CASE 4—A woman of 70 suffering from advanced cerebral arteriosclerosis with many bilateral thrombotic episodes When given mist. kaolin et morph 15 ml in the morning and senokot tabs 1 at night she continued to have nocturnal incontinence, but on reversing the order of the drugs, this disappeared

CASE 5—A woman of 78 She was incontinent of fæces following a right hemiparesis two months ago As with case 4 she continued to have nocturnal incontinence when the drugs were given in the usual order, but since being given senokot tabs 1 in the morning and mist kaolin et morph 15 ml at night she has remained continent

Provided that fæcal impaction is always excluded by careful digital examination, this regime seems to have considerable value in the management of elderly patients with fæcal incontinence

PERTHES' DISEASE

SIR,—Professor Trueta in his rejoinder (April 2) to the letter by Dr Palmer and myself (in which we stated that we not infrequently saw cases of Perthes' disease) cited various references about this condition in Negro subjects The works quoted came from the Southern States of the United States of America and Argentina It is certainly of interest to note that in these areas people of Negro origin do not appear to suffer from Perthes' However, in contrast, the condition is not unduly rare in Western Nigeria, Northern Nigeria, Ghana, Jamaica, and Southern Rhodesia I base this statement on personal experience and discussion with orthopædic surgeons and other radiologists practising in these areas The statistical figures culled by Professor Trueta are from the Negro populations originating from the Congo basin, whereas the Nigerian, Ghanaian, and West Indian (Jamaica) are from the Guinea Coast It may well be that this difference in geographical origin is also reflected in a genetic factor that may protect some individuals from the ravages of Perthes' disease

I feel that Perthes' disease is as common here as in Europe, though of course it is very difficult to base any statistics on hospital experience, which may not reflect the pattern of the population as a whole

University College Hospital,
Ibadan, Nigeria

W P COCKSHOTT

SIR,—I should like to disagree with Professor Trueta in his statement that " the Negro child appears to be immune to Perthes' " I have seen Dr Cockshott's cases and have 9 of my own with normal hæmoglobin studies and followed through the development and resolution of the condition [1]

This seem to be yet another instance where one cannot say a condition never occurs in a particular race but merely shows a reduced incidence

University College of the West Indies,
Mona St Andrew, Jamaica

J S R GOLDING

PSYCHIATRIC DAY HOSPITALS

SIR,—The letter of April 9 from Dr Richard Fox and his colleagues should be generally welcomed, firstly for adding information on a subject in which it is inadequate, and secondly for its emphasis on the need for further research However, they have perhaps taken a rather over-cautious approach—for instance, in their limit of a half-hour's journey to the day hospital Many day patients have a considerably longer journey than this and make it willingly, in order to obtain treatment without the necessity for admission Is it also neccessary to insist that patients are unable to carry on their normal lives before offering them the benefits of day-hospital treatment ?

In our present situation, with psychiatric facilities so generally inadequate, a day hospital can only become inactive if it is in the wrong place or if it has failed to establish links with the community around, so that they are unaware of its existence or function If " strategically " placed, they should be adequately served by public transport, special hospital transport would add very considerably to the expense

---

[1] Goodman, L. S , Gilman, A The Pharmacological Basis of Therapeutics, p 229 New York, 1958

[2] Fairbairn, J W *Brit med J* 1958, i, 218

[1] *J Bone Jt Surg* 1959, 41B, 4

Whilst it is true that we have little definite information on the cost per patient-illness of day patients as against inpatients, there can be no doubt that as far as capital cost is concerned, there is an immense advantage in day hospitals They can readily be converted out of existing buildings or can be accommodated in relatively cheap temporary structures In the present state of uncertainty as to the future arrangement of psychiatric services, they can therefore provide a great deal of treatment, without much capital commitment If experience from the first few years working of the Mental Health Act should prove that, in fact, other kinds of hospital provision were more suitable, these buildings could then be scrapped with very little loss Inpatient units must inevitably require capital expenditure on a much greater scale, causing rigidity in planning, in the same way that 19th-century mental hospitals do today This aspect of the question is discussed in the report by Farndale which is shortly to be published, and which is likely to supply much ammunition for these controversies

Littlemore Hospital,
Oxford
H L FREEMAN

REINFORCEMENT OF IMMUNITY TO DIPHTHERIA

SIR,—In a symposium [1] on immunisation in childhood two speakers advocated the use of toxoid-antitoxin floccules (T A F) to reinforce immunity against diphtheria I was somewhat surprised to see no mention of another floccule antigen, alkali-dissolved floccules (D F), which has been used with satisfaction in South Africa for 10 years

It is employed as the secondary stimulus in those people who have received $AlPO_4$—adsorbed floccules (A D F) as a primary stimulus, and as a booster in older children, adolescents, and adults

D F and T A F are tolerated by the body to the same extent, but D F has certain advantages It is more easily prepared, is more antigenic, is water clear, its toxoid content can be found by the flocculation test, and it contains much less protein of equine origin

Either the publications [2–4] referring to A D F and D F have escaped the notice of the British authorities or, as concerns the use of D F as a reinforcing injection, they have found disadvantages of which we in South Africa are unaware It would be interesting to have their views

P B PEACOCK

CHEMOTHERAPY OF MYELOMA AND MULTIPLE MYELOMA

SIR,—Do myeloma and multiple myeloma respond differently to chemotherapy ? Descriptions of the chemotherapeutic control of both diseases indicate little difference in the responses

Nabarro [5] noted no response in a patient with multiple myeloma who was given the nitrogen mustard, HN2, and no benefit was observed in another patient with myeloma given the aromatic mustard, R48 Marchal et al [6] reported clinical remissions in 3 out of 4 patients with myeloma, following treatment with corticotrophin (A C T H) and cortisone, and a slight response in 1 patient with multiple myeloma on the same therapy Fadda et al [7] described remissions of 6 to 24 months in a case of myeloma and several cases of multiple myeloma given urethane, corticotrophin, cortisone, and radiotherapy

A comparison, however, of the results of treating 495 patients with multiple myeloma with a group of patients described by 30 other investigators as having myeloma reveals some interesting differences in response to chemotherapy [8] Some of these differences are as follows

Chemicals	*Multiple myeloma* *No of cases*	*No of remissions*	*Myeloma* *No of cases*	*No of remissions*
Urethane	222	160	1	1
A C T H /cortisone	64	31	19	9
Stilbenes	41	17	31	26
Tretamine	36	6	5	3
N-mustards	30	20	11	9
Radiophosphorus	17	7	35	14

Diamond [9] and others have pointed out the difficulty of recognising clinically solitary plasmocytoma, and undoubtedly a number of the cases of myeloma described in the literature are disseminated plasma-cell myelomas or multiple myelomas There is need for more controlled studies on the response of these malignant diseases to chemotherapeutic agents before it can be declared that a difference does exist

JOHN R SAMPEY

HYPERCALCIURIA IN WILSON'S DISEASE (HEPATICOLENTICULAR DEGENERATION)

SIR,—In 1959 we reported hypercalciuria in 4 of 5 patients with Wilson's disease [10] Of the 4 patients, 1 had bilateral nephrocalcinosis and another had a calculus in the left kidney

We have since had the opportunity to study another patient with Wilson's disease who had hypercalciuria, thus confirming our original observation

A 27-year-old white man with œdema and jaundice was first seen at the Mayo Clinic in July, 1959 In 1956 he had noted some enlargement of his breasts He felt well otherwise until the middle of 1958 when he began to tire easily and to gain weight In May, 1959, he became jaundiced and was found to have œdema of his legs and ascites About that time, he first noted a tremor of his hands That same month he was admitted to the hospital and found to have impending hepatic coma His condition improved and he was dismissed from the hospital the next month After he returned home, however, his condition worsened and in July he registered at the clinic

Physical examination revealed a slight static tremor of the hands and some slurring of speech Typical Kayser-Fleischer rings were present as well as left pleural effusion, ascites, and œdema of the legs The lower edge of the liver was palpable at the level of the umbilicus The lower edge of the spleen was 4 fingerbreadths below the left costal margin.

Laboratory investigations —Prothrombin-time, 37 sec , concentration of bilirubin per 100 ml serum, 0 direct and 2 74 mg indirect, cholesterol-cephalin flocculation test, 4+ , thymol turbidity 7 units, alkaline-phosphatase 15 6 King-Armstrong units, uric acid 1 7 mg , calcium 8 4 and 8 0 mg , and inorganic phosphate 3 3 mg per 100 ml serum, cholesterol 153 mg per 100 ml plasma, copper-oxidase activity present in the serum, total proteins, 4 94 g per 100 ml serum with electrophoretic fractions of 1 57 g albumin, 0 26 g alpha-1-globulin, 0 34 g alpha-2-globulin, and 2 77 g beta and gamma globulin combined

X-rays of the thorax showed a large pleural effusion on the left side The renal areas did not show evidence of nephrocalcinosis or renal calculus

The daily urinary excretion of calcium and other materials was measured for three days during which time the patient was given a diet containing an average of 213 mg of calcium, 2 93 mg of copper, 62 g of protein, 111 g of fat, and 244 g of carbohydrate per twenty-four hours and distilled water as desired During this period, the urinary excretions of calcium were 317, 331, and 258 mg (average 302 mg) per twenty-four hours Over the same three-day period the average urinary excretion of phosphorus was 829 mg , copper 0 23 mg , and alpha-amino-nitrogen 414 mg , all per twenty-four hours

[10] Litin R B Randall R V Goldstein, N P , Power, M H Diessner G R. *Amer J med Sci* 1959, 238, 614

With the diet used in this study, a value for urinary calcium in excess of 170 mg per twenty-four hours is above normal By this criterion, the patient had hypercalciuria

It is not known whether the hypercalciuria in this patient and in our other 4 patients was caused primarily by increased absorption of calcium from the gastrointestinal tract, by a renal defect, or by a skeletal disease The hypercalciuria was not associated with hypercalcæmia or known skeletal disease.

Additional study is necessary to determine the cause and frequency of hypercalciuria in Wilson's disease Since it is well known that renal tubular dysfunction may be present in Wilson's disease, the hypercalciuria may represent another renal tubular defect

THE PERSONAL DOCTOR

SIR,—The review of the state of general practice here and in the U S.A. by Dr Fox is a most important contribution to the subject It raises and stimulates much thought.

I am quite certain that there is much more to general practice today in Great Britain under the N.H S than just "personal doctoring", which is after all an essential technique of all good medical and surgical practice

The clinical opportunities in general practice offer the doctor almost unlimited scope Dr Fox tends to assume, or that is the impression he gives me, that real and proper medicine can only be practised in the atmospheres of hospitals and clinics, and that all that is left the G P are a mass of trivia and the personal support and comfort of the individual patient. I find this not to be the case in my own practice, which must also be the experience of others

In a survey of referrals in my practice I found that I was able to manage and care for almost 95% of the work in any year Admittedly I have access to local X-ray and pathology departments, but the point I want to make is that there is no real need to think in terms of beds and clinics to be able to practise good general practice In the same study [1] I showed that many serious diseases such as pneumonias, coronary occlusions, and anæmias do not need admission to hospital This is general practice as I see it, looking after and coping with the vast majority of disease in my community To it must be added an appreciation of natural history of disease in a longitudinal sense, the appreciation of the patient as an individual, of the influences of environment and social factors

As for the G.P getting back into the hospitals and having G.P beds in which to treat his own patients, I personally am still not convinced that this is necessary to improve standards I wonder how many G.P s *really* want this Facilities for investigating one's own patients, yes, but when I have done all I can at home, with help of the district nurse, there is little else that I, as a G P , would be able to do if I was looking after that same patient in a hospital bed. When I refer a patient for admission I feel that the patient requires the full facilities of the hospital set-up, with housemen and consultants playing their part. I certainly could not be on 24-hour call to care for my patients in hospital and to put up drips and carry out other emergency procedures as well as look after my practice, and I think it would be bad in principle to expect the houseman to take orders from me as well as his consultant chief What is required now before further action is taken on this important matter is to carry out a realistic review of what goes on in G P hospitals at present, just as Forsyth and Logan have done in Barrow on other hospitals [2] and see precisely what types of cases are being treated in these hospitals and why

Dr Fox has not convinced me that drastic changes are required in British general practice The basic principles of personal and family doctoring plus general medical care for 95% of the illnesses of the community seem to me to be potentially the best in the world What we do need is to see how improvements can be made in the existing type of practice To do this we need to define the faults and the problems still more clearly and more simply and then to devise and try possible remedies

The last few words of Dr Fox's essay are most important "let us adopt—or rather resume—their excellent habit of wide experiment"

Beckenham, Kent JOHN FRY

SIR,—Like Dr John Hunt (April 9), I should like to take issue with Dr Fox on this notion of the "extinct general practitioner' It may be true of the urban species, of whom I am not qualified to speak it is certainly not true of the rural, who has as much honest doctoring to do as ever in the past three decades and has, increasingly, to bully and badger his consultant friends into doing, or getting done, what needs to be done for those of his patients who require hospital services

I should like to know more of the functions envisaged by Dr Fox for the "personal" doctor, who sounds to me less of a doctor than a sort of medical curate, one who visits, exchanges ideas, throws out suggestions, but, in fact, accomplishes precisely nothing of therapeutic value

Dr Fox stresses the importance of time spent on the sick man and, of course, he is right—when the man is really sick. But if he—or, more often, she—is merely bellyaching about trivialia he should, for the good of his soul, be kindly but firmly dealt with and speedily dismissed.

It is here that the G P who speaks as one having authority can do something to alleviate the panics produced by publicity and discourage that morbid and humourless preoccupation with health which is now the bane of mankind

Crediton, Devon L N JACKSON

*** Dr Fox writes "The length of my article must have obscured my meaning I want the personal doctor to practise the same kind of responsible and skilful medicine as Dr Jackson and Dr Fry"—ED L

SIR,—We must be grateful to Dr Fox for his account of the current practices in the U S.A We are sure that all will see from this the inherent dangers of "impersonal doctoring"

As an adjective "personal" must refer to any medical man worthy of the name doctor, irrespective of whether he be general practitioner or specialist It is not the prerogative of either one alone to administer "T.L C." Where the general practitioner has the advantage over the specialist, and always will have, is in that the former maintains daily contact with every department of medicine, and the latter does not. Consequently, as the number of true consultants diminish, and they are replaced by highly trained specialists, he is the principal remaining source of a balanced medical knowledge and opinion The latter is much prized by the patient, who is often in doubt about advice proffered by the specialist.

The specialist, on the other hand, remains particularly competent in his own department, but his knowledge and experience outside of it becomes progessively more vestigial This, we would suggest, makes him the person least able to assess the competence of colleagues in other fields, and what their limitations should be, whether general practitioner or specialist

---

[1] Fry, J *Brit med J* 1959, ii

[2] Forsyth, G , Logan, R F L Demand for Medical Care. Nuffield Provincial Hospitals Trust, 1960 See *Lancet*, April 16, 1960, p 871

If there are to be any restrictions on practice, they should be clearly defined, at the time of registration, by the G M C Thereafter, a doctor's practice should depend entirely on his ability to build a reputation for himself in his selected specialty, one of which is general practice No person, or persons in whatever guise, or for whatever end, should be allowed to restrict a practitioner arbitarily in his selected field, unless negligent practice can be demonstrated In all specialties it must be left to the doctor to decide whether he thinks himself capable of managing a particular case or whether he needs help We feel sure that consultants, and specialists of consultant rank, would be the first to resist a direction that they were not capable of handling certain cases in their own specialty

Llantwit Major,
Glamorgan

NORMAN R SALES
PETER H THOMAS

SIR,—Dr Fox, after studying the American medical scene, draws what I believe are wrong conclusions as to the future of general practice in this country He rightly makes his point, that unless the family doctor is seen still to perform some important function for which independence is necessary he will eventually be absorbed into the hospital system But thereafter Dr Fox seeks to put back the clock by perpetuating the picture of the family physician practising from his own home or in partnership in the traditional way

Under the National Health Scheme, with the State paying the bill, the relationship is no longer between doctor and patient but is now between doctor, State, and patient The community expects the profession to practise efficiently, and, however personal our predecessors were in their attentions, they could never be described as efficient in terms of modern preventive medicine as measured by mortality and morbidity rates

The modern general practitioner cannot practise efficiently on his own from his own home He is a member of a team, a team with ancillary helpers all skilled in their own professions and the closer the team works the better

General practice must evolve into group practice or health-centre practice where, with nurses, secretaries, laboratory aids, and health visitors, the family doctor can fully utilise the modern means of preventive medicine

Dr Fox, like Canute of old, seeks to hold back the tide

Darbishire House Health Centre,
Manchester

H W ASHWORTH

Parliament

Royal Commission's Recommendations Accepted

IN a written answer on April 11, Mr DEREK WALKER-SMITH, the Minister of Health, announced that the Government were prepared to accept as a whole the recommendations of the Royal Commission on Medical and Dental Remuneration, provided that the doctors and dentists were ready to accept them on the same basis Representatives of the professions had been informed Mr Walker-Smith said

> We have drawn attention to various matters which are an integral part of full acceptance of the recommendations, including the establishment of a standing body to keep medical and dental remuneration under review on the lines proposed by the Commission For a number of reasons, however, it is not possible to adopt the Commission's proposal that the Inland Revenue should furnish the review body with comprehensive information about professional earnings generally, but the Government are confident that the review body will be able to obtain the necessary information by other means, such as sample inquiries, and will of course be ready to give the body any help to this end that lies within their power
>
> The preliminary discussions we have had with representatives of the professions have been helpful and we have been able to clarify a number of points We have offered as the next step to arrange for the proposals to be worked out in detail jointly by officers of our departments with representatives of the professions in order that as clear and comprehensive a picture as possible of their practical effect may be put before their members We understand, however, that before this offer to engage in detailed discussions can be accepted it will need to be put to the professions through their appropriate channels It is our hope that the professions will reach their decisions, and that discussions will begin, as soon as possible
>
> It is estimated that the extra annual cost falling on the Exchequer if the proposals are agreed will be about £11½ million net The extra cost which would fall in 1960–61 is, however, estimated at £41½ million net, because the payments recommended by the Commission in that year and because of other temporary features

The council of the British Medical Association have announced that they will recommend the special representative meeting on May 19 to accept the Minister's offer and his invitation " to enter into detailed discussions by means of joint working parties "

Training of Nurses

On March 13 Mr KENNETH ROBINSON prayed against a Statutory Instrument which would permit the reintroduction of a minimum educational standard for entry into most parts of the nursing profession,[1] because, despite the General Nursing Council's wish that the change should apply to all parts of the nursing profession, the Minister had excluded mental nurses This decision would perpetuate old prejudices and seemed to support the idea of a two-class nursing system It was no secret that the Minister and his advisers had disregarded the Council's advice because, despite recent improvements, recruitment to mental nursing was still far from adequate It would be a disaster to erect an educational barrier which might exclude many potential recruits who would ultimately make admirable nurses There were many excellent mental nurses—and, Mr Robinson believed, general nurses, too—who had the right sort of temperament, the energy, the understanding, and the intelligence to do the nurse's job admirably, but who lacked the educational qualifications, and perhaps even the kind of aptitude needed to obtain them He agreed with the Minister's reasons for excluding mental nurses It would be highly dangerous to limit in any way the intake of mental nursing students But the status and prestige of the mental nurse within the profession would be further damaged by this new distinction, and this would have a detrimental effect on recruitment In the circumstances he suggested that it was wrong to introduce an educational standard, at any rate at present, even in general nursing He believed that it would have a serious effect on recruitment there, too In the London teaching hospitals there was no recruitment problem, but the hospitals of the industrial areas of the North were forced, if they were to have any student nurses, to take nearly all comers who showed some aptitude for nursing The avowed policy of the G N C was to train more assistant nurses and fewer nurses He feared that we might well be in danger of finding ourselves at the end of the day with a small highly trained elite and an inadequate rank and file to back it up He had never believed that entry into any profession ought to be limited to those who could be expected or might be expected to reach the top

Miss PITT replied that the Minister had consulted all the hospital authorities before approving the change, and it was generally felt that the reintroduction of a minimum educational standard was desirable to cut down wastage. It was possible to make the change now because of the improvement in recruiting and the "bulge" of 18-year-olds But the staffing situation in the psychiatric hospitals was not yet sufficiently established to make it right for the Minister to reach a decision, now, that the educational requirement should become compulsory in them on July 1, 1962, as it would in other hospitals Where they were prepared to do so, it was open to psychiatric hospitals to apply the educational requirement to their student nurse entry straight away, and the Minister would be glad to see as many as possible do so He intended to keep the matter under close review in the light of experience of the way in which the new educational standard worked in practice, including experience gained by psychiatric hospitals in applying the new standard on a voluntary basis, and a fresh assessment of the position in the psychiatric hospitals would not necessarily be postponed until after July 1, 1962

---

[1] See *Lancet*, April 2, 1960 p 761

Population (Statistics) Bill

At the report stage of this Bill on April 12 Mr **Derek Walker-Smith**, the Minister of Health, introduced a new clause which put on a statutory footing the reporting to Parliament of the statistics derived under the 1938 Act and the information about stillbirths as expanded by the present Bill. This expansion of the basis of statistical information and its reporting would help research and subsequent genetic evaluation. By recording the cause of death of stillbirths in England and Wales it was expected, he said, that about 3800 stillbirths and 3400 deaths after birth would be available each year for the study of congenital malformations With the Scottish figures, this would give a total of about 8200 cases a year, which would be enough to allow the necessary research to be undertaken. With these figures, we might hope that in due time we should be able to determine the porportions and types of congenital abnormalities due to genetic defects It would then be possible to investigate what factors were responsible for producing these genetic defects, and to find the proportion of cases due to the workings of genetic defects long present in the race, compared with those due to newly arisen genetic change.

The tables relating to the causes of stillbirth would be published in Part I of the Registrar General's *Annual Review* In Part 3 of the review there would be a comment and explanation of the new information authorised in the Bill The date for introducing the collection of information about stillbirths would be advanced to July 1

Dr **Edith Summerskill** regretted that the new clause did not ask for a yearly report from the Medical Research Council or at least a full report in the Minister's annual review

The Bill was read a third time.

Obituary

ARCHIBALD HECTOR McINDOE

Kt, C.B.E., M.B N Z, M.S, M.Sc. Minnesota, F R.C.S, F.A.C.S

When the war began in 1939 Sir Archibald McIndoe's reputation was already firmly established among his colleagues in this country By the time the war ended, through his work for casualties at East Grinstead, his professional renown was international and he had grateful patients in every part of the world. He died on April 12 at the age of 59

Stoneman

He was born and educated in New Zealand, and graduated M.B from the University of Otago in 1923 Almost at once he joined the staff of the Mayo Foundation at Rochester, where he worked with Charles and William Mayo and Counsellor His seven years at the Mayo Clinic showed immense industry and promise, and he made important contributions to the pathology of the liver and the surgery of the biliary tract. In 1930 he decided to seek his fortune in England, and, under the compelling influence of Sir Harold Gillies, he turned his back on general surgery and took up the almost unrecognised specialty of plastic surgery Hard work was always part of his nature. He had already acquired the degrees of M.SC. and M.S from the University of Minnesota and the F.A.C.S, and he now quickly gained the English F.R.C.S Within a short time he was appointed to the staff of St. Bartholomew's Hospital

At that time there were only two other consultants who gave all their time to plastic surgery, and McIndoe seized the opportunity to develop the specialty, taking his full share both in technical advances and in the establishment of new policies During the pre-war decade he published important papers on hypospadias, congenital absence of the vagina, mammaplasty, facial reconstruction after cancer, cleft lip, fractures of the mandible, lymphœdema, cartilage grafting, and the surgical treatment of X-ray burns They all bore the hallmark of his capacity for hard work, his questing imagination, and his mastery of technique. It was at this phase of his career that the war came. A year earlier he had been made civilian consultant to the R.A.F, and he was at once appointed to the new E.M S unit for burns and maxillofacial injuries at East Grinstead as surgeon in charge.

A colleague, to whom we are indebted for much of this notice, adds the following personal tribute.

"Much has been written of McIndoe's work on burned airmen, and sometimes the subject has perhaps been treated with false emphasis In fact it was a striking achievement; technically he mastered many problems—the massive grafting of burned eyelids, and the relief of hyperextension deformities of the hands, to name but two—while in the psychological and economic aspects of morale he was deeply perceptive. He had, and consciously developed, an exceptional knack for earning the confidence of young airmen, and he quickly came to terms of close friendship with many of them. Some were brilliant and tragic figures like Richard Hillary, some were ordinary youngsters with unexciting personalities and few gifts Both types felt at ease with him

"At the same time he knew how to persuade men occupying high positions in the direction of the war to provide facilities which he deemed essential to the treatment and (above all) to the rehabilitation of these burned and disfigured patients Despite two serious operations during the war, he travelled extensively and wherever he went brought not only invaluable clinical guidance but also that boundless optimism and energy which were his particular genius After the war honours crowded in upon him, from Holland, Poland, Czechoslovakia, and France, and perhaps a knighthood in 1946 meant less to him than his vice-presidency of the Royal College of Surgeons. During the last fifteen years of his life, his enormous energies proved equal to a vast number of claims on his time, and in very recent days, tireless as ever, he was busy initiating a new department for research into problems of homografting

"Yet all these activities—administrative, literary, and clinical—were but one side of a man of bustling and untiring energy The immensely gifted surgeon turned easily to the cheerful company of his friends and his home. He was proud of his possessions and eager to enjoy them and share them. Believing that busy men should relax with energetic recreations, he was seldom happier than when pursuing big game in East Africa, whether with rifle or camera. Those who lived with him on holiday have described a different person—still eager and acquisitive, but leisured and serene There are few corners of the world that will not share this country's sadness in the loss of so gay, so dynamic, and so dedicated a man "

Of McIndoe's work for the Royal College of Surgeons J P R writes

" By his own exertions and enterprise he made for himself a place and a function in the college which it will be difficult if not impossible to fill When he first joined the council he started, as everyone does, in a very quiet way, though it was noticeable from the outset how methodical he was with his paper work, and how punctilious in attending to the various duties allotted to him He was rightly critical of the number and complexity of our committees, and during his term as vice-president an attempt was made to simplify the procedure of college business

" His clear head and incisive speech made him an excellent committee man, and when he was in the chair the work went very smoothly and expeditiously because it had been well thought-out by him beforehand He was not very interested in the academic side of college life and the consideration of the arrangements for courses of lectures and other forms of teaching frankly bored him, as did arguments about university routine and regulations

" He had two major interests—the training of surgeons, and in particular the training of young plastic surgeons, for which purpose a special organisation was set up in the college to give advice to the Ministry of Health about the staffing of the centres for plastic surgery in England and Wales, and the financing of the college both for its reconstruction after the war and for its maintenance

" He made a great success of his period of office as chairman of the finance committee, but undoubtedly his greatest contribution to the welfare of the college, the benefits of which will be enjoyed for many a long day if not ' for ever ', was his attracting to the college laymen who were willing and soon became enthusiastic to further its scientific work, and who were able to give substantial and even princely donations to make the buildings grow and the work continue McIndoe had a clear view of the ideals for which the college is striving, and he had the supreme gift of being able to fire other people, both professional and lay, with his own enthusiasm to join with him and his colleagues in the council in the pursuit of these ideals

" Though it looked as though this sort of evangelistic endeavour came easy to him, in fact it cost him a very great deal in thought, in time, in concentrated effort to persuade a doubtful and hard-headed businessman that this was the best outlet for his charitable benefactions, in fact, in the end it cost him his life, for apart from his professional work at East Grinstead and in London he concentrated his whole energy, physical and mental, on working for the college Little wonder that his colleagues cannot bring themselves to believe that he is gone! The least they can do in respect for his memory is to redouble their effort to finish the work he started so well and so nearly completed "

By his first marriage, which was dissolved, Sir Archibald had two daughters In 1954 he married as his second wife Mrs Constance Belcham, who survives him

WILLIAM RODNEY FORRESTER-WOOD

M A , M B Cantab , F R C S

Mr W R Forrester-Wood, senior general surgeon in the Brighton and Lewes and Mid-Sussex hospital groups, died on April 6 at the age of 57

His father was a general-practitioner surgeon in Southport He originally wished to enter the Army, but the loss of sight in one eye at the age of 12 prevented this He was educated at Cheltenham, Caius College, Cambridge, and St Bartholomew's Hospital After qualifying in 1929, he held house-appointments at Addenbrooke's Hospital, Brighton Infirmary, and the Royal Sussex County Hospital He took the F R C S in 1932, and remained in Brighton in consulting practice He was elected to the staff of the Royal Sussex County Hospital, and he was also appointed surgeon to the Royal Alexandra Children's Hospital in Brighton, and the Haywards Heath and other Sussex hospitals He was on the hospital management committee of the Brighton and Lewes hospital group and for some years was the chairman of its medical and medical-staff committees

W A B writes

" Forrester-Wood's special interest was children's surgery, but he took up thoracic surgery in the '30s and performed major operations in that specialty as a routine—with the exception of valvulotomy, which he consistently refused to undertake He was in wide demand for private work over a large area, and his judgment, technical ability, and personality made him popular and trusted by doctors and patients alike He was the unchallenged and universal choice as chairman of medical and medical-staff committees, for his colleagues had implicit trust in him, and his outwardly calm temperament, firmness, and humour controlled many difficult situations

" His responsibilities were extensive and heavy, and in 1958 he had a myocardial infarction He recovered reasonably and after a year returned to committee work, though no longer as chairman, and was still heavily relied on But physical limitations returned, so that even his beloved fishing became a labour The loss of this able and trusted man will be keenly felt, for he combined the values of the older generation with the judgment and abilities of the new "

Mr Forrester-Wood leaves a widow and a son

Dr J J COULTHARD

Two friends add their tributes to the obituary of Dr. Coulthard which appeared last week

" He was a man who gave his best at all times to anyone in trouble," writes D L B " No-one worked harder or had higher standards To him all men were equal "

H W S W , a surgical colleague, says " I learnt to regard him as one of the best general practitioners I have ever met

His devotion to his patients was almost obsessive, but it was tempered with knowledge, insight, and rare judgment, a blend of qualities which gave him just the right degree of detachment without obscuring his interest and humanity

He managed to get through his work by getting up very early and was seldom in bed before midnight His daily round was never hurried and often interrupted by the innumerable acts of personal kindness which will be long remembered by his friends and patients "

Dr J C BROOM

C R R , one of Dr Broom's younger friends, who had already corresponded with him from Malaya for three years, writes of their first meeting in 1956

" I remember a slightly diminutive, very kindly, elderly man with a grey toothbrush moustache and sparkling rather boyish eyes I was impressed by his scholarly air and intense interest in his work, he was never too busy to discuss some aspect or to explain a problem I was given access to all his reference files, and through him accorded many privileges throughout the Wellcome Institute He set an example in his industriousness and passionate dedication to honesty and endeavour He considered science as a high cultural value, and this was evident in his delightfully lucid style of writing, and interest in the historical aspects of medicine He felt strongly the responsibility of the older to the younger person, and his advice on personal problems was straightforward and honest His friendly encouragement and sympathetic understanding has since sustained me several times, and I will miss seeing him when I visit England "

Notes and News

A DISPOSABLE FACE MASK

To prevent droplet infection, a new disposable mask has been evolved which, we are informed, prevents bacteria-laden particles from passing sideways as well as forwards from the wearer's mouth. Embodying an impervious layer of paper, this mask has been tested at the Children's Hospital, Birmingham, and Dr K. B. Rogers, clinical pathologist to the hospital, has given us some particulars.

After the masks had been worn for over an hour, tests were made at quarter-hour intervals, as follows:

A petri dish containing 10% blood-agar medium was held about 12 in. in front of the wearer's mouth and "tut" was spoken ten times, in a normal but slightly raised voice. A second blood-agar plate was held in the same position while a single explosive "spraying spit"[1] was emitted.

None of the plates exposed during these experiments grew any organisms. "Though this result was no better than that obtained with the standard cotton mask used in this hospital which has a sheet of 'Cellophane' inserted between two layers of cotton fabric, further testing showed that the disposable masks had certain advantages. The cotton-fabric masks are square and they tend to leave a slight gap on either side of the wearer's nose where the nose protrudes from the face. The disposable mask is shaped to fit snugly round the nose. Plates held at right-angles to the wearer's mouth grew no organisms when the disposable mask was worn, but always grew organisms when the standard hospital mask was in place."

The disposable mask[2] is easily put in position and can be kept there with a cotton-covered strip of elastic which is sealed into the free edges of the mask and is so arranged that two loops of thin elastic can be placed round the wearer's ears.

When the masks were autoclaved in the hospital's theatre autoclave at 20 lb pressure (126°C) the texture of the elastic was slightly altered, so that it was liable to stretch when pulled out to place it round the ears. But this did not happen when they were autoclaved at 10 or 15 lb. pressure (155° and 121°C).

These masks were unsuitable for anyone who had a cold with profuse nasal discharge, for the paper becomes sodden and liable to tear. But, as Dr Rogers says, "it is not suggested that people with heavy colds should be on duty."

COOPERATIVE GERIATRICS

LAST year the National Corporation for the Care of Old People announced that they were going to compile a register of social and medical research on the welfare of old people. This year[3] they are able to announce that a master copy of the register is now in existence and can be consulted at their offices. It includes projects that are being made by universities, hospitals, local authorities, voluntary organisations, and individuals. It is hoped that printed copies will be ready for distribution in the next few months. Though the register may not be absolutely complete, it is a substantial and useful start which, the corporation points out, shows "not only what is being done but what is not."

College of General Practitioners

Upjohn travelling fellowships—Applications are invited from members of this college for not less than 15 fellowships of up to £200 each in value.

These fellowships are to enable general practitioners to spend a minimum of two weeks' postgraduate study at their old teaching hospitals or at any other hospitals, clinics, health centres, or general practices in the United Kingdom or Eire. They are not available for study overseas. Further information may be had from the secretary of the college, 41, Cadogan Gardens, London, S.W.3. The closing date for applications is Aug. 1.

University of Durham

Dr R. J. Scothorne, senior lecturer in anatomy in the University of Glasgow, has been appointed to the chair of anatomy at King's College.

Dr Scothorne, who is 39 years of age, was educated at the Royal Grammar School, Newcastle upon Tyne, and Leeds University. He graduated B.SC. with honours in anatomy in 1941 and continued his studies at the University of Chicago with a Rockefeller studentship. He graduated M.D. Chicago in 1943, and on his return to this country the following year he took the degree of M.B. Leeds with honours. He was lecturer in anatomy at Leeds from 1945 to 1950 when he took up his present post at Glasgow. In 1951 he took the degree of M.D. with distinction, and in 1955 he was awarded the Struthers gold medal. His published work includes papers on the comparative embryology of the thyroid gland and the thymus, on tissue transplantation immunity, and on salt and water balance in birds.

National University of Ireland

Dr O. T. D. Loughnan has been appointed lecturer in therapeutics at University College, Cork.

The degree of M.D. has been conferred on J. M. Lavelle.

Royal College of Surgeons of England

At a meeting of the council on April 14, with Sir James Paterson Ross, the president, in the chair, Prof. G. V. R. Born was admitted as Vandervell professor of pharmacology.

The following, as medical practitioners of twenty years' standing, were elected fellows of the college without examination:

Dr Frankis Evans, Surgeon Capt. J. L. S. Coulter, Dr E. F. Scowen, Dr T. J. Warren (Brazil), Prof. E. C. Amoroso, Prof. Jannie Louw (Cape Town).

The Jacksonian prize for 1959 was awarded to Mr G. Slaney. Dr B. Orban of Chicago was appointed Webb-Johnson lecturer for 1958–61, and Mr R. G. Smith, Laming Evans senior research fellow in orthopædics.

The following were elected fellows in the Faculty of Anæsthetists without examination:

J. Boreau (France), W. G. Cullen (Canada), J. U. Forbes (Kuwait), R. Frey (Germany), M. Prasad (India).

Jephcott Lecture

This lecture will be given by Sir Howard Florey on Monday, May 9, at 7 P.M., at 1, Wimpole Street, London, W.1. His subject will be coronary-artery disease. Tickets may be had from the secretary of the Jephcott Lecture Trust, 1, Carlos Place, W.1.

Central Midwives Board

Mr Arnold Walker has been re-elected chairman and Prof. A. A. Moncrieff deputy chairman of the board.

British Council for Rehabilitation

The annual general meeting of this Council will be held on Thursday, May 12, at 3 P.M., in H.Q.S. Wellington, Temple Stairs, Victoria Embankment, London, W.C.2. Sir Harry Platt will give the Dame Georgiana Buller lecture. He will speak on pioneers of rehabilitation.

Committee on Noise

The 12 members of the committee which the Government has set up to consider noise and its effects will include Dr. T. Ferguson Rodger, professor of psychological medicine in Glasgow University, who will act as *deputy chairman*, and Dr R. C. M. Pearson, medical officer of health for Newcastle upon Tyne.

Provision of Animals for Cancer Research

A symposium on this subject will be held at 1, Wimpole Street, London, W.1, on Monday, May 23, at 9.30 A.M., with Prof. J. S. Mitchell in the chair.

The speakers will include Prof. Alexander Haddow, Dr P. R. Peacock, Dr D. L. Woodhouse, Prof. F. Bergel, Dr P. Loustalot (Basle), Dr M. H. Salaman, Dr K. E. K. Rowson, Dr George E. Jay, Jr (Bethesda), Dr J. G. Bennette, Dr June East, Dr J. G. Carr, Dr F. Kingsley Sanders, and Mr J. D. Whittaker. Further information may be had from the director, Laboratory Animals Centre, M.R.C. Laboratories, Woodmansterne Road, Carshalton, Surrey.

[1] Studies in Air Hygiene. *Spec. Rep. Ser. med. Res. Coun., Lond.* no. 262, Table 12. 1948.

[2] This mask is being marketed by Smith & Nephew—Southalls Ltd., 256, Old Street, London, E.C.1, and will be called "S and N Disposable Promask."

[3] Twelfth annual report of the corporation. (Nuffield Lodge, Regent's Park, London, N.W.1.)

International Conference on Congenital Malformations

This conference will be held in London from July 18 to 22 (see *Lancet*, Feb 13, 1960, p 375) Registration forms may be had from the secretariat of the conference, 67, New Bond Street, Dering Yard, London, W 1, and should be returned not later than May 1

The International Society for Clinical and Experimental Hypnosis

Prof Alexander Kennedy has been elected the first president of the British national division of this society, Mr Eric E Woolley, chairman of council, Dr Michael Fenton, hon treasurer, and Dr A A Mason (24, Avenue Road, Regent's Park, London, N W 8), hon secretary

Medical Association for the Prevention of War

On Saturday, May 28, at 2.30 P.M, at 45, Russell Square, London, W C 1, this Association will hold a symposium on the present-day significance of medical science in relation to war prevention The speakers will include Dr Anthony Storr and Dr Jeffrey Boss The hon secretary of the association is Dr Dorothy Arning, 127, King Henry's Road, N W 3

Colour Television Demonstrations

Demonstrations, arranged by the Kensington and Hammersmith division of the British Medical Association and the West London faculty of the College of General Practitioners, will be transmitted from the Postgraduate Medical School of London and the Hammersmith Hospital to an audience at the Royal College of Surgeons of England, Lincoln's Inn Fields, W C 2, at 8 30 P M from Monday to Thursday, May 16 to 19 The subjects chosen for demonstrations are repair of hiatus hernia, pituitary ablation, heart surgery, and dermatology Further particulars may be had from the secretary of the B M.A, B M.A House, Tavistock Square, W C 1

A few scholarships (in the form of free accommodation and board) are offered to medical students who wish to attend the international summer course to be held from July 15 to 30 at the Institute of Hydrology and Climatology of the University of Clermont-Ferrand Applications should be sent to the director of the institute, Boulevard Gergovia, Clermont-Ferrand, France

The annual general meeting of the Kent Pædiatric and Child Health Society will be held on Saturday, May 7, at 3 P M, at Maidstone Technical School for Girls, Albion Place, Maidstone Dr A D B Clarke will speak on uses and abuses of the I Q test

A semipermanent exhibition, arranged by Dr E J Moynahan, on pædiatric dermatology will be held at the Institute of Dermatology, Lisle Street, W C 2, from May 2 to 25

The London Medical Orchestra is giving a concert on Saturday, April 30, at 8 P.M at the Royal College of Surgeons, Lincoln's Inn Fields, W C 2, in aid of the Imperial Cancer Research Fund
